MIPS® Architecture For Programmers Volume III: MIPS64® / microMIPS64™ Privileged Resource Architecture, Rev. 6.03

IMAGINATION TECHNOLOGIES PROPRIETARY / RESTRICTED CONFIDENTIAL - HEIGHTENED STANDARD OF CARE REQUIRED AS PER CONTRACT

Table of Contents

Chapter 1: About This Book	15
1.1: Typographical Conventions	16
1.1.1: Italic Text	16
1.1.2: Bold Text	16
1.1.3: Courier Text	16
1.2: UNPREDICTABLE and UNDEFINED	16
1.2.1: UNPREDICTABLE	16
1.2.2: UNDEFINED	17
1.2.3: UNSTABLE	17
1.3: Special Symbols in Pseudocode Notation	17
1.4: For More Information	20
Chapter 2: The MIPS64 and microMIPS64 Privileged Resource Architecture	21
2.1: Introduction	21
2.2: The MIPS Coprocessor Model	21
2.2.1: CP0 - The System Coprocessor	21
2.2.2: CP0 Registers	21
Chapter 3: MIPS64 and microMIPS64 Operating Modes	23
3.1: Debug Mode	23
3.2: Kernel Mode	23
3.3: Supervisor Mode	24
3.4: User Mode	24
3.5: Other Modes	24
3.5.1: 64-bit Address Enable	24
3.5.2: 64-bit Operations Enable	24
3.5.3: 64-bit Floating-Point Operations Enable	25
3.5.4: 64-bit FPR Enable	25
3.5.5: Coprocessor 0 Enable	25
3.5.6: ISA Mode	26
Chapter 4: Virtual Memory	27
4.1: Differences between Releases of the Architecture	27
4.1.1: Virtual Memory	27
4.1.2: Physical Memory	27
4.1.3: Protection of Virtual Memory Pages	27
4.1.4: Context Register	28
4.1.5: Segmentation Control	28
4.1.6: Enhanced Virtual Addressing	28
4.2: Terminology	28
4.2.1: Address Space	28
4.2.2: Segment and Segment Size (SEGBITS)	28
4.2.3: Physical Address Size (PABITS)	29
4.3: Virtual Address Spaces	29
4.4: Compliance	32
4.5: Access Control as a Function of Address and Operating Mode	32

4.6: Address Translation and Cacheability and Coherency Attributes for the kseg0 and kseg1 Segments	34
4.7: Address Translation and Cacheability-and-Coherency Attributes for the xkphys Segment	35
4.8: Address Translation for the kuseg Segment when Status _{ERL} = 1	37
4.9: Special Behavior for the kseg3 Segment when Debug _{DM} = 1	38
4.10: Special Behavior for Data References in User Mode with Status _{UX} = 0	38
4.11: 32-bit Compatibility Addressing for Release 5 EVA, and Release 6	39
4.11.1: Use Cases for Effective_Address Generation Function	42
4.12: TLB-Based Virtual Address Translation	42
4.12.1: Address Space Identifiers (ASID)	42
4.12.2: TLB Organization	42
4.12.3: TLB Initialization	43
4.12.4: Address Translation	46
4.13: Segmentation Control	52
4.13.1: Exception Behavior under Segmentation Control	56
4.14: Enhanced Virtual Addressing	61
4.14.1: EVA Segmentation Control Configuration	61
4.14.2: Enhanced Virtual Address (EVA) Instructions	63
4.15: Hardware Page Table Walker	65
4.15.1: Multi-Level Page Table support	66
4.15.2: PTE and Directory Entry Format	71
4.15.3: Hardware page table walking process	73
Chapter 5: Common Device Memory Map	81
5.1: CDMMBase Register	81
5.2: CDMM - Access Control and Device Register Blocks	82
5.2.1: Access Control and Status Registers	83
Chapter 6: Interrupts and Exceptions	85
6.1: Interrupts	85
6.1.1: Interrupt Modes	86
6.1.2: Generation of Exception Vector Offsets for Vectored Interrupts	95
6.2: Exceptions	96
6.2.1: Exception Priority	97
6.2.2: Exception Vector Locations	98
6.2.3: General Exception Processing	100
6.2.4: EJTAG Debug Exception	103
6.2.5: Reset Exception	103
6.2.6: Soft Reset Exception	104
6.2.7: Non Maskable Interrupt (NMI) Exception	105
6.2.8: Machine Check Exception	106
6.2.9: Address Error Exception	106
6.2.10: TLB Refill and XTLB Refill Exceptions	107
6.2.11: Execute-Inhibit Exception	109
6.2.12: Read-Inhibit Exception	109
6.2.13: TLB Invalid Exception	110
6.2.14: TLB Modified Exception	111
6.2.15: Cache Error Exception	112
6.2.16: Bus Error Exception	113
6.2.17: Integer Overflow Exception	113
6.2.18: Trap Exception	114
6.2.19: System Call Exception	114
6.2.20: Breakpoint Exception	114
6.2.21: Reserved Instruction Exception	115

6.2.22: Coprocessor Unusable Exception.....	116
6.2.23: MDMX Unusable Exception	116
6.2.24: Floating-Point Exception	116
6.2.25: Coprocessor 2 Exception	117
6.2.26: Watch Exception	117
6.2.27: Interrupt Exception	118
Chapter 7: GPR Shadow Registers	119
7.1: Introduction to Shadow Sets.....	119
7.2: Support Instructions.....	120
Chapter 8: CP0 Hazards	121
8.1: Introduction.....	121
8.2: Types of Hazards	121
8.2.1: Possible Execution Hazards	121
8.2.2: Possible Instruction Hazards.....	123
8.3: Hazard Clearing Instructions and Events	123
8.3.1: MIPS64 Instruction Encoding.....	124
8.3.2: microMIPS64 Instruction Encoding.....	125
Chapter 9: Coprocessor 0 Registers	127
9.1: Coprocessor 0 Register Summary	127
9.2: Notation	133
9.3: Writing CPU Registers.....	133
9.4: Index Register (CP0 Register 0, Select 0).....	135
9.5: VPControl (CP0 Register 0, Select 4)	137
9.6: Random Register (CP0 Register 1, Select 0).....	139
9.7: EntryLo0, EntryLo1 (CP0 Registers 2 and 3, Select 0)	141
9.8: Global Number Register (COP0 Register 3, Select 1)	151
9.9: Context Register (CP0 Register 4, Select 0)	153
9.10: ContextConfig Register (CP0 Register 4, Select 1).....	157
9.11: UserLocal Register (CP0 Register 4, Select 2)	159
9.12: Debug ContextID (CP0 Register 4, Select 4)	161
9.13: XContextConfig Register (CP0 Register 4, Select 3)	163
9.14: PageMask Register (CP0 Register 5, Select 0)	165
9.15: PageGrain Register (CP0 Register 5, Select 1)	169
9.16: SegCtl0 (CP0 Register 5, Select 2)	175
9.17: SegCtl1 (CP0 Register 5, Select 3)	175
9.18: SegCtl2 (CP0 Register 5, Select 4)	175
9.18.1: xkphys access mode override.....	177
9.19: PWBase Register (CP0 Register 5, Select 5)	181
9.20: PWField Register (CP0 Register 5, Select 6)	181
9.21: PWSize Register (CP0 Register 5, Select 7).....	184
9.22: Wired Register (CP0 Register 6, Select 0)	191
9.23: PWCtl Register (CP0 Register 6, Select 6)	193
9.24: HWREna Register (CP0 Register 7, Select 0)	197
9.25: BadVAddr Register (CP0 Register 8, Select 0).....	199
9.26: BadInstr Register (CP0 Register 8, Select 1).....	201
9.27: BadInstrP Register (CP0 Register 8, Select 2).....	203
9.28: Count Register (CP0 Register 9, Select 0).....	205
9.29: Reserved for Implementations (CP0 Register 9, Selects 6 and 7)	205
9.30: EntryHi Register (CP0 Register 10, Select 0).....	207

9.31: Compare Register (CP0 Register 11, Select 0).....	211
9.32: Reserved for Implementations (CP0 Register 11, Selects 6 and 7)	211
9.33: Status Register (CP Register 12, Select 0)	213
9.34: IntCtl Register (CP0 Register 12, Select 1)	225
9.35: SRSCtl Register (CP0 Register 12, Select 2).....	229
9.36: SRSSMap Register (CP0 Register 12, Select 3)	233
9.37: Cause Register (CP0 Register 13, Select 0)	235
9.38: NestedExc (CP0 Register 13, Select 5)	241
9.39: Exception Program Counter (CP0 Register 14, Select 0)	243
9.39.1: Special Handling of the EPC Register in Processors that Implement MIPS16e ASE or microMIPS64 Base Architecture	243
9.40: Nested Exception Program Counter (CP0 Register 14, Select 2)	245
9.41: Processor Identification (CP0 Register 15, Select 0)	247
9.42: EBase Register (CP0 Register 15, Select 1).....	249
9.43: CDMMBase Register (CP0 Register 15, Select 2)	253
9.44: CMGCRBase Register (CP0 Register 15, Select 3).....	255
9.45: BEVVA Register (CP0 Register 15, Select 4)	257
9.46: Configuration Register (CP0 Register 16, Select 0)	259
9.47: Configuration Register 1 (CP0 Register 16, Select 1)	263
9.48: Configuration Register 2 (CP0 Register 16, Select 2)	267
9.49: Configuration Register 3 (CP0 Register 16, Select 3)	271
9.50: Configuration Register 4 (CP0 Register 16, Select 4)	279
9.51: Configuration Register 5 (CP0 Register 16, Select 5)	285
9.52: Reserved for Implementations (CP0 Register 16, Selects 6 and 7)	293
9.53: Load Linked Address (CP0 Register 17, Select 0)	295
9.54: Memory Accessibility Attribute Register (CP0 Register 17, Select 1)	298
9.55: Memory Accessibility Attribute Register Index (CP0 Register 17, Select 2).....	305
9.56: WatchLo Register (CP0 Register 18)	307
9.57: WatchHi Register (CP0 Register 19).....	309
9.58: XContext Register (CP0 Register 20, Select 0).....	311
9.59: Reserved for Implementations (CP0 Register 22, all Select values).....	315
9.60: Debug Register (CP0 Register 23, Select 0).....	317
9.61: Debug2 Register (CP0 Register 23, Select 6).....	319
9.62: DEPC Register (CP0 Register 24)	321
9.62.1: Special Handling of the DEPC Register in Processors That Implement the MIPS16e ASE or microMIPS64 Base Architecture	321
9.63: Performance Counter Register (CP0 Register 25)	323
9.64: ErrCtl Register (CP0 Register 26, Select 0)	329
9.65: CacheErr Register (CP0 Register 27, Select 0)	331
9.66: TagLo Register (CP0 Register 28, Select 0, 2)	333
9.67: DataLo Register (CP0 Register 28, Select 1, 3).....	335
9.68: TagHi Register (CP0 Register 29, Select 0, 2).....	337
9.69: DataHi Register (CP0 Register 29, Select 1, 3)	339
9.70: ErrorEPC (CP0 Register 30, Select 0)	341
9.70.1: Special Handling of the ErrorEPC Register in Processors That Implement the MIPS16e ASE or microMIPS64 Base Architecture	341
9.71: DESAVE Register (CP0 Register 31).....	343
9.72: KScratchn Registers (CP0 Register 31, Selects 2 to 7)	345

Appendix A: Alternative MMU Organizations	347
A.1: Fixed Mapping MMU	347
A.1.1: Fixed Address Translation	347
A.1.2: Cacheability Attributes	350

A.1.3: Changes to the CP0 Register Interface	351
A.2: Block Address Translation	351
A.2.1: BAT Organization	351
A.2.2: Address Translation.....	352
A.2.3: Changes to the CP0 Register Interface	353
A.3: Dual Variable-Page-Size and Fixed-Page-Size TLBs	353
A.3.1: MMU Organization.....	353
A.3.2: Programming Interface	355
A.3.3: Changes to the TLB Instructions	356
A.3.4: Changes to the COP0 Registers	357
A.3.5: Software Compatibility	358

Appendix B: Revision History	361
---	------------

List of Figures

About This Book

The MIPS® Architecture For Programmers Volume III: MIPS64® / microMIPS64™ Privileged Resource Architecture consists of the following documents:

- Volume I-A describes conventions used throughout the document set, and provides an introduction to the MIPS64® Architecture
- Volume I-B describes conventions used throughout the document set, and provides an introduction to the microMIPS64™ Architecture
- Volume II-A provides detailed descriptions of each instruction in the MIPS64® instruction set
- Volume II-B provides detailed descriptions of each instruction in the microMIPS64™ instruction set
- Volume III describes the MIPS64® and microMIPS64™ Privileged Resource Architecture which defines and governs the behavior of the privileged resources included in a MIPS® processor implementation
- Volume IV-a describes the MIPS16e™ Application-Specific Extension to the MIPS64® Architecture. Beginning with Release 3 of the Architecture, microMIPS is the preferred solution for smaller code size.
- Volume IV-b describes the MDMX™ Application-Specific Extension to the MIPS64® Architecture and microMIPS64™. With Release 5 of the Architecture, MDMX is deprecated. MDMX and MSA can not be implemented at the same time.
- Volume IV-c describes the MIPS-3D® Application-Specific Extension to the MIPS® Architecture
- Volume IV-d describes the SmartMIPS® Application-Specific Extension to the MIPS32® Architecture and the microMIPS32™ Architecture and is not applicable to the MIPS64® document set nor the microMIPS64™ document set.
- Volume IV-e describes the MIPS® DSP Module to the MIPS® Architecture
- Volume IV-f describes the MIPS® MT Module to the MIPS® Architecture
- Volume IV-h describes the MIPS® MCU Application-Specific Extension to the MIPS® Architecture
- Volume IV-i describes the MIPS® Virtualization Module to the MIPS® Architecture
- Volume IV-j describes the MIPS® SIMD Architecture Module to the MIPS® Architecture

1.1 Typographical Conventions

This section describes the use of *italic*, **bold** and `courier` fonts in this book.

1.1.1 Italic Text

- is used for *emphasis*
- is used for *bits*, *fields*, *registers*, that are important from a software perspective (for instance, address bits used by software, and programmable fields and registers), and various *floating point instruction formats*, such as *S*, *D*, and *PS*
- is used for the memory access types, such as *cached* and *uncached*

1.1.2 Bold Text

- represents a term that is being **defined**
- is used for **bits** and **fields** that are important from a hardware perspective (for instance, **register** bits, which are not programmable but accessible only to hardware)
- is used for ranges of numbers; the range is indicated by an ellipsis. For instance, **5..1** indicates numbers 5 through 1
- is used to emphasize **UNPREDICTABLE** and **UNDEFINED** behavior, as defined below.

1.1.3 Courier Text

`Courier` fixed-width font is used for text that is displayed on the screen, and for examples of code and instruction pseudocode.

1.2 UNPREDICTABLE and UNDEFINED

The terms **UNPREDICTABLE** and **UNDEFINED** are used throughout this book to describe the behavior of the processor in certain cases. **UNDEFINED** behavior or operations can occur only as the result of executing instructions in a privileged mode (i.e., in Kernel Mode or Debug Mode, or with the CP0 usable bit set in the *Status* register). Unprivileged software can never cause **UNDEFINED** behavior or operations. Conversely, both privileged and unprivileged software can cause **UNPREDICTABLE** results or operations.

1.2.1 UNPREDICTABLE

UNPREDICTABLE operations can cause a result to be generated or not. **UNPREDICTABLE** operations can cause arbitrary exceptions. **UNPREDICTABLE** results or operations have several implementation restrictions:

- Implementations of operations generating **UNPREDICTABLE** results must not depend on any data source (memory or internal state) that is inaccessible in the current processor mode.
- **UNPREDICTABLE** operations must not read, write, or modify the contents of memory or an internal state that is inaccessible in the current processor mode. For example, **UNPREDICTABLE** operations executed in user

mode must not access memory or an internal state that is only accessible in Kernel Mode or Debug Mode or in another process.

- **UNPREDICTABLE** operations must not halt or hang the processor.

1.2.2 UNDEFINED

UNDEFINED operations or behavior can have no impact, or they can create an environment in which execution can no longer continue. **UNDEFINED** operations or behavior can cause data loss.

UNDEFINED operations or behavior must not cause the processor to enter a state from which there is no exit other than powering down the processor (hang). The assertion of any of the reset signals must restore the processor to an operational state.

1.2.3 UNSTABLE

A sampling of an **UNSTABLE** value results in a legal transient value that was correct at some time prior to the sampling. Implementations of operations generating **UNSTABLE** results must not depend on any data source (memory or internal state) which is inaccessible in the current processor mode.

1.3 Special Symbols in Pseudocode Notation

Algorithmic descriptions of an operation are described as pseudocode in a high-level language notation resembling Pascal. [Table 1.1](#) lists the special symbols used in the pseudocode notation.

Table 1.1 Symbols Used in Instruction Operation Statements

Symbol	Meaning
\leftarrow	Assignment.
$=, \neq$	Tests for equality, inequality.
\parallel	Bit string concatenation.
x^y	A y -bit string formed by y copies of the single-bit value x .
$b\#n$	A constant value n in base b . For instance $10\#100$ represents the decimal value 100, $2\#100$ represents the binary value 100 (decimal 4), and $16\#100$ represents the hexadecimal value 100 (decimal 256). If the "b#" prefix is omitted, the default base is 10.
$0bn$	A constant value n in base 2. For example: $0b100$ represents the binary value 100 (decimal 4).
$0xn$	A constant value n in base 16. For example: $0x100$ represents the hexadecimal value 100 (decimal 256).
$x_{y..z}$	Selection of bits y through z of bit string x . Little-endian bit notation (rightmost bit is 0) is used. If y is less than z , this expression is an empty (zero length) bit string.
$+, -$	2's complement or floating-point arithmetic: addition, subtraction.
$*, \times$	2's complement or floating-point multiplication (both used for either).
div	2's complement integer division.
mod	2's complement modulo.
$/$	Floating-point division.
$<$	2's complement less-than comparison.
$>$	2's complement greater-than comparison.

Table 1.1 Symbols Used in Instruction Operation Statements (Continued)

Symbol	Meaning
\leq	2's complement less-than or equal comparison.
\geq	2's complement greater-than-or-equal comparison.
nor	Bitwise logical NOR.
xor	Bitwise logical XOR.
and	Bitwise logical AND.
or	Bitwise logical OR.
not	Bitwise inversion.
&&	Logical (non-bitwise) AND.
<<	Logical shift left (shift in zeros at right-hand-side).
>>	Logical shift right (shift in zeros at left-hand-side).
GPRLen	The length, in bits (32 or 64), of the CPU general-purpose registers.
$GPR[x]$	CPU general-purpose register x . The content of $GPR[0]$ is always zero. In Release 2 of the Architecture, $GPR[x]$ is a short-hand notation for $SGPR[SRSCtl_{CSS}, x]$.
$SGPR[s,x]$	From Release 2 on of the Architecture, multiple copies of the CPU general-purpose registers can be implemented. $SGPR[s,x]$ refers to GPR set s , register x .
$FPR[x]$	Floating-point operand register x
$FCC[CC]$	Floating-point condition code CC . $FCC[0]$ has the same value as $COC[1]$.
$FPR[x]$	Floating-point (coprocessor unit 1), general register x
$CPR[z,x,s]$	Coprocessor unit z , general register x , select s .
CP2CPR[x]	Coprocessor unit 2, general register x .
$CCR[z,x]$	Coprocessor unit z , control register x .
CP2CCR[x]	Coprocessor unit 2, control register x .
$COC[z]$	Coprocessor unit z condition signal.
$Xlat[x]$	Translation of the MIPS16e GPR number x into the corresponding 32-bit GPR number.
BigEndianMem	Endian mode as configured at chip reset (0 for little-endian, 1 for big-endian). Specifies the endianness of the memory interface (see LoadMemory and StoreMemory pseudocode function descriptions), and the endianness of Kernel and Supervisor mode execution.
BigEndianCPU	The endianness for load and store instructions (0 for little-endian, 1 for big-endian). In User mode, this endianness can be switched by setting the RE bit in the <i>Status</i> register. Thus, BigEndianCPU can be computed as (BigEndianMem XOR ReverseEndian).
ReverseEndian	Signal to reverse the endianness of load and store instructions. This feature is available in User mode only. It is implemented by setting the RE bit of the <i>Status</i> register. Thus, ReverseEndian can be computed as (SR_{RE} and User mode).
$LLbit$	Bit of virtual state used to specify operation for instructions that provide atomic read-modify-write. $LLbit$ is set when a linked load occurs and is tested by the conditional store. It is cleared (by exception return instructions) during other CPU operation, when a store to the location is no longer atomic.

Table 1.1 Symbols Used in Instruction Operation Statements (Continued)

Symbol	Meaning						
I , I+n , I-n :	<p>This is a prefix to <i>Operation</i> description lines and functions as a label. It indicates the instruction time during which the pseudocode appears to “execute.” Unless otherwise stated, all effects of the current instruction appear to occur during the instruction time of the current instruction. No label is equivalent to a time label of I. Sometimes, effects of an instruction appear to occur either earlier or later (during the instruction time of another instruction). When this happens, the instruction operation is written in sections labeled with the instruction time relative to the current instruction I, in which the effect of that pseudocode appears to occur. For example, an instruction can have a result that is not available until after the next instruction. Such an instruction has the portion of the instruction operation description that writes the result register in a section labeled I+1.</p> <p>The effect of pseudocode statements for the current instruction labelled I+1 appears to occur “at the same time” as the effect of pseudocode statements labeled I for the following instruction. Within one pseudocode sequence, the effects of the statements take place in order. However, between sequences of statements for different instructions that occur “at the same time,” there is no defined order. Programs must not depend on a particular order of evaluation between such sections.</p>						
PC	<p>The <i>Program Counter</i> value. During the instruction time of an instruction, this is the address of the instruction word. The address of the instruction that occurs during the next instruction time is determined by assigning a value to <i>PC</i> during an instruction time. If no value is assigned to <i>PC</i> during an instruction time by any pseudocode statement, it is automatically incremented by either 2 (in the case of a 16-bit MIPS16e instruction) or 4 before the next instruction time. A taken branch assigns the target address to the <i>PC</i> during the instruction time of the instruction in the branch delay slot.</p> <p>In the MIPS Architecture, the <i>PC</i> value is only visible indirectly, such as when the processor stores the restart address into a GPR on a jump-and-link or branch-and-link instruction, or into a Coprocessor 0 register on an exception. The <i>PC</i> value contains a full 64-bit address, all bits of which are significant during a memory reference.</p>						
ISA Mode	<p>In processors that implement the MIPS16e Application Specific Extension or the microMIPS base architectures, the <i>ISA Mode</i> is a single-bit register that determines the mode in which the processor is executing.</p> <table border="1"> <thead> <tr> <th>Encoding</th><th>Meaning</th></tr> </thead> <tbody> <tr> <td>0</td><td>32-bit MIPS instructions.</td></tr> <tr> <td>1</td><td>MIPS16e or microMIPS instructions.</td></tr> </tbody> </table> <p>In the MIPS Architecture, the <i>ISA Mode</i> value is only visible indirectly, such as when the processor stores a combined value of the upper bits of <i>PC</i> and the <i>ISA Mode</i> into a GPR on a jump-and-link or branch-and-link instruction, or into a Coprocessor 0 register on an exception.</p>	Encoding	Meaning	0	32-bit MIPS instructions.	1	MIPS16e or microMIPS instructions.
Encoding	Meaning						
0	32-bit MIPS instructions.						
1	MIPS16e or microMIPS instructions.						
PABITS	Represents the number of physical address bits implemented by the symbol PABITS. If 36 physical address bits are implemented, the size of the physical address space is $2^{\text{PABITS}} = 2^{36}$ bytes.						
SEGBITS	Represents the number of virtual address bits implemented in a segment of the address space. If 40 virtual address bits are implemented in a segment, the size of the segment is $2^{\text{SEGBITS}} = 2^{40}$ bytes.						
FP32RegistersMode	<p>Indicates whether the FPU has 32-bit or 64-bit floating point registers (FPRs). In MIPS32 Release 1, the FPU has thirty-two 32-bit FPRs in which 64-bit data types are stored in even-odd pairs of FPRs. In MIPS64 (and, optionally, in MIPS32 Release2 and Release 3), the FPU has 32 64-bit FPRs in which 64-bit data types are stored in any FPR.</p> <p>In MIPS32 Release 1 implementations, FP32RegistersMode is always a 0. MIPS64 implementations have a compatibility mode in which the processor references the FPRs as if it were a MIPS32 implementation. In this case, FP32RegistersMode is computed from the FR bit in the <i>Status</i> register. If this bit is a 0, the processor operates as if it had thirty-two 32-bit FPRs. If this bit is a 1, the processor operates with thirty-two 64-bit FPRs.</p> <p>The value of FP32RegistersMode is computed from the FR bit in the <i>Status</i> register.</p>						

Table 1.1 Symbols Used in Instruction Operation Statements (Continued)

Symbol	Meaning
InstructionInBranchDelaySlot	Indicates whether the instruction at the Program Counter address was executed in the delay slot of a branch or jump. This condition reflects the <i>dynamic</i> state of the instruction, not the <i>static</i> state. The value is false if a branch or jump occurs to an instruction whose PC immediately follows a branch or jump, but which is not executed in the delay slot of a branch or jump.
SignalException(exception, argument)	Causes an exception to be signaled using the exception parameter as the type of exception, and the argument parameter as an exception-specific argument. Control does not return from this pseudocode function; the exception is signaled at the point of the call.

1.4 For More Information

Various MIPS RISC processor manuals and additional information about MIPS products can be found at the MIPS URL: <http://www.mips.com>

For comments or questions on the MIPS64® Architecture or this document, send email to support@mips.com.

The MIPS64 and microMIPS64 Privileged Resource Architecture

2.1 Introduction

The MIPS64 and microMIPS64 Privileged Resource Architecture (PRA) provides the mechanisms to manage the resources of the CPU: virtual memory, caches, exceptions, and user contexts. The effects of some components of the PRA, such as the virtual memory layout, are user-visible. Many other components are visible only to the operating system kernel and to systems programmers.

2.2 The MIPS Coprocessor Model

The MIPS ISA provides for up to four coprocessors. A coprocessor extends the functionality of the MIPS ISA, while sharing the instruction fetch and execution control logic of the CPU. Some coprocessors, such as the system coprocessor and the floating-point unit, are standard parts of the ISA and are specified as such in the architecture documents. Coprocessors are generally optional, with one exception: CP0, the system coprocessor, is required. CP0 is the ISA interface to the PRA and provides full control of the processor state and modes.

2.2.1 CP0 - The System Coprocessor

CP0 provides an abstraction of the functions necessary to support an operating system: exception handling, memory management, scheduling, and control of critical resources. The interface to CP0 is through various instructions encoded with the *COP0* opcode, including the ability to move data to, and from, the CP0 registers, as well as specific functions that modify CP0 state. The CP0 registers and the interaction with them make up much of the PRA.

2.2.2 CP0 Registers

The CP0 registers provide the interface between the ISA and the PRA. The CP0 registers are described in [Chapter 9, “Coprocessor 0 Registers”](#) on page 127.

MIPS64 and microMIPS64 Operating Modes

The MIPS64 and microMIPS64 PRA requires two operating modes: User Mode and Kernel Mode. In User Mode, the programmer can access the CPU and FPU registers that are provided by the ISA, as well as a flat, uniform virtual memory address space. In Kernel Mode, the system programmer can access the full capabilities of the processor, as well as change the virtual memory mapping, control the system environment, and context switch between processes.

The MIPS PRA also supports the implementation of two additional modes: Supervisor Mode and EJTAG Debug Mode. See the EJTAG specification for a description of Debug Mode.

Release 2 of the MIPS64 Architecture added support for 64-bit coprocessors (and, in particular, 64-bit floating-point units) with 32-bit CPUs. Thus, certain floating-point instructions that previously were enabled by 64-bit operations on a MIPS64 processor now are enabled by new 64-bit floating-point operations. Release 3 introduced the microMIPS instruction set, allowing all microMIPS processors to implement a 64-bit floating-point unit.

The MIPS64 and microMIPS64 PRA provide backward-compatible support for 32-bit programs. They do this by providing enables for both 64-bit addressing and 64-bit operations. If access is not enabled, an attempt to reference a 64-bit address, or an instruction that implements a 64-bit operation, results in an exception.

3.1 Debug Mode

For processors that implement EJTAG, the processor is operating in Debug Mode if the DM bit in the CP0 *Debug* register is 1. If the processor is in Debug Mode, it has full access to all resources that are available to Kernel Mode operations.

3.2 Kernel Mode

The processor is in Kernel Mode when the *DM* bit in the *Debug* register is 0 (if the processor implements Debug Mode), and any of the following is true:

- The *KSU* field in the CP0 *Status* register contains 0b00.
- The *EXL* bit in the *Status* register is 1.
- The *ERL* bit in the *Status* register is 1.

The processor enters Kernel Mode at power-up, or as the result of an interrupt, exception, or error. The processor leaves Kernel Mode and enters User Mode or Supervisor Mode when all of the previous three conditions are false, usually as the result of an ERET instruction.

3.3 Supervisor Mode

The processor is operating in Supervisor Mode (if that optional mode is implemented by the processor) when all of the following are true:

- The *DM* bit in the *Debug* register is 0 (if the processor implements Debug Mode).
- The *KSU* field in the *Status* register contains 0b01.
- The *EXL* and *ERL* bits in the *Status* register are both 0.

3.4 User Mode

The processor is operating in User Mode when all of the following are true:

- The *DM* bit in the *Debug* register is 0 (if the processor implements Debug Mode).
- The *KSU* field in the *Status* register contains 0b10.
- The *EXL* and *ERL* bits in the *Status* register are both 0.

3.5 Other Modes

3.5.1 64-bit Address Enable

Access to 64-bit addresses are enabled under any of the following conditions:

- A legal reference to a kernel address space occurs, and the *KX* bit in the *Status* register is 1.
- A legal reference to a supervisor address space occurs, and the *SX* bit in the *Status* register is 1.
- A legal reference to a user address space occurs, and the *UX* bit in the *Status* register is 1.

Note that the operating mode of the processor is not relevant to 64-bit address enables. That is, a reference to user address space made while the processor is operating in Kernel Mode is controlled by the state of the *UX* bit, not by the *KX* bit.

An attempt to reference a 64-bit address space when 64-bit addresses are not enabled results in an Address Error Exception (either AdEL or AdES, depending on the type of reference).

When a TLB miss occurs, the choice of the Exception Vector is also determined by the 64-bit address enable¹. If 64-bit addresses are not enabled for the reference, the TLB Refill Vector is used. If 64-bit addresses are enabled for the reference, the XTLB Refill Vector is used.

3.5.2 64-bit Operations Enable

Instructions that perform 64-bit operations are legal under any of the following conditions:

-
1. For ksseg/sseg access while in supervisor mode, see Note 2 of [Table 4.2](#).

- The processor is operating in Kernel Mode, Supervisor Mode, or Debug Mode, as described above.
- The PX bit in the *Status* register is 1.
- The processor is operating in User Mode, as described above, and the UX bit in the *Status* register is 1.

The last two bullets imply that 64-bit operations are legal in User Mode when either the PX bit or the UX bit is 1 in the *Status* register.

Trying to execute an instruction that performs 64-bit operations when such instructions are not enabled results in a Reserved Instruction Exception.

3.5.3 64-bit Floating-Point Operations Enable

Instructions that are implemented by a 64-bit floating-point unit are legal under any of the following conditions:

- In an implementation of Release 1 of the Architecture, 64-bit floating-point operations are enabled only if 64-bit operations are enabled.
- In an implementation of Release 2 or later of the , 64-bit floating-point operations are enabled if the *F64* bit in the *FIR* register is 1. The processor must also implement the floating-point data type. Release 3 introduced the microMIPS instruction set; on all microMIPS processors, 64-bit floating-point operations are enabled if the F64 bit in the *FIR* register is 1.

3.5.4 64-bit FPR Enable

Access to 64-bit FPRs is controlled by the *FR* bit in the *Status* register. If the *FR* bit is 1, the FPRs are interpreted as thirty-two 64-bit registers that can contain any data type. If the *FR* bit is 0, the FPRs are interpreted as thirty-two 32-bit registers, any of which can contain a 32-bit data type (W, S). In this case, 64-bit data types are contained in even-odd pairs of registers.

In Release 1 of the Architecture , 64-bit FPRs are supported in a MIPS64 processor. In Release 2 of the Architecture, 64-bit FPRs are supported in a 64-bit floating-point unit, for both MIPS32 and MIPS64 processors. From Release 3 and later of the Architecture, 64-bit FPRs are supported for all processors, including all microMIPS processors. As of Release 5 of the Architecture, if floating-point is implemented, then *FR*=1 is required; that is, the 64-bit FPU, with the *FR*=1 64-bit FPU register model, is required. The *FR*=0 32-bit FPU register model continues to be required.

The operation of the processor is **UNPREDICTABLE** under the following conditions:

- The *FR* bit is 0, 64-bit operations are enabled, and a floating-point instruction is executed whose datatype is L or PS.
- The *FR* bit is 0, and an odd register is referenced by an instruction whose datatype is 64 bits.

3.5.5 Coprocessor 0 Enable

Access to Coprocessor 0 registers are enabled under any of the following conditions:

- The processor is running in Kernel Mode or Debug Mode, as defined above.
- The *CU0* bit in the *Status* register is 1.

3.5.6 ISA Mode

Release 3 of the Architecture introduced a second branch of the instruction set family, microMIPS64. Devices can implement both ISA branches (MIPS64 and microMIPS64) or only one branch.

The ISA Mode bit is used to specify which ISA branch to use when decoding instructions. This bit is normally not visible to software. Its value is saved to any GPR used as a jump target address, such as GPR31 when written by a JAL instruction, or the source register for a JR instruction.

For processors that implement the MIPS64 ISA, the ISA Mode bit value of zero selects MIPS64. For processors that implement the microMIPS64 ISA, the ISA Mode bit value of 1 selects microMIPS64. For processors that implement the MIPS16e™ ASE, the ISA Mode bit value of 1 selects MIPS16e. A processor is not allowed to implement both MIPS16e and microMIPS.

Please read *Volume II-B: Introduction to the microMIPS64 Instruction Set*, Section 5.3, “ISA Mode Switch” for a detailed description of ISA mode switching between the ISA branches and the ISA Mode bit.

Virtual Memory

4.1 Differences between Releases of the Architecture

4.1.1 Virtual Memory

In Release 1 of the Architecture, the minimum page size was 4 kB, with optional support for pages as large as 256 MB. In Release 2 of the Architecture (and subsequent releases), optional support for 1 kB pages was added for use in specific embedded applications that require access to pages smaller than 4 kB. Such usage is expected to be in conjunction with a default page size of 4 kB and is not intended, or suggested, to replace the default 4 kB page size; rather, to augment it.

Support for 1 kB pages involves the following changes:

- Addition of the *PageGrain* register. This register is also used by the SmartMIPS™ ASE specification, but bits used by Release 2 of the Architecture and those used by the SmartMIPS ASE specification do not overlap.
- Modification of the *EntryHi* register to enable writes to, and use of, bits 12..11 (*VPN2X*).
- Modification of the *PageMask* register to enable writes to, and use of, bits 12..11 (*MaskX*).
- Modification of the *EntryLo0* and *EntryLo1* registers to shift the *Config3_{SP}* field to the left by two bits, when 1 kB page support is enabled, to create space for two lower-order physical address bits.

Support for 1 kB pages is denoted by the *Config3_{SP}* bit; it is enabled by the *PageGrain_{ESP}* bit.

4.1.2 Physical Memory

In Release 1 of the Architecture, the physical address size was limited by the format of the *EntryLo0* and *EntryLo1* registers to 36 bits. Some applications of MIPS processors require more than 36 bits of physical address (for example, high-end networking), and others are expected. Thus, Release 2 added an optional extension to the architecture to provide up to 59 bits of physical address for MIPS64 processors. This extension is optional because several operating systems currently use the reserved bits to the left of the *PFN* field in the *EntryLo0* and *EntryLo1* registers for PTE software flags. The flags are loaded directly into these registers on a TLB Refill exception. Thus, for compatibility with existing software, the extension of the *PFN* field must be done with an explicit enable.

Support for extended PFNs is denoted by the *Config3_{LPA}* bit and enabled by the *PageGrain_{ELPA}* bit.

4.1.3 Protection of Virtual Memory Pages

In Release 3 of the Architecture, two optional control bits are added to each TLB entry. These bits, *RI* (*Read Inhibit*) and *XI* (*Execute Inhibit*), allow more types of protection to be used for virtual pages, including write-only pages and non-executable pages.

This feature originated in the SmartMIPS ASE but has been modified from the original SmartMIPS definition. For the Release 3 version of this feature, each of the *RI* and *XI* bits can be separately implemented. For the Release 3 version of this feature, new exception codes are used when a TLB access does not obey the *RI/XI* bits.

4.1.4 Context Register

In Release 3 of the Architecture, the *Context/XContext* registers are a read/write registers containing a address pointer to an arbitrary power-of-two aligned data structure in memory, such as an entry in the page table entry (PTE) array. In Releases 1 and 2, this pointer was defined to reference a fixed-sized 16-byte structure in memory within a linear array containing an entry for each even/odd virtual page pair. The Release 3 version of the *Context/XContext* registers can be used more generally.

This feature originated in the SmartMIPS ASE. This feature is optional in the Release 3 version of the base architecture.

4.1.5 Segmentation Control

In Release 3 of the Architecture includes an optional programmable segmentation feature. This improves the flexibility of the MIPS virtual address space.

With Segmentation Control, address translation begins by matching a virtual address to the region specified in a Segment Configuration. Thus, the virtual address space is definable as the set of memory regions specified by Segment Configurations. The behavior and attributes of each region are also specified by Segment Configurations. Six Segment Configurations are defined, fully mapping the 32-bit Compatible virtual address space.

4.1.6 Enhanced Virtual Addressing

In Release 3 of the Architecture has an optional Enhanced Virtual Addressing (EVA) feature. EVA is a configuration of Segmentation Control and a set of kernel mode load/store instructions allowing direct access to user-mode memory space from kernel mode. In EVA, Segmentation Control is programmed to define two address ranges, a three-GB range with mapped-user, mapped-supervisor, and unmapped-kernel access modes, and a one-GB address range with mapped-kernel access mode.

4.2 Terminology

4.2.1 Address Space

An *Address Space* is the range of all possible addresses that can be generated for a particular addressing mode. There is one 64-bit Address Space and one 32-bit Compatibility Address Space that is mapped into a subset of the 64-bit Address Space.

4.2.2 Segment and Segment Size (SEGBITS)

A *Segment* is a defined subset of an Address Space that has self-consistent reference and access behavior. A 32-bit Compatibility Segment is part of the 32-bit Compatibility Address Space and is either 2^{29} or 2^{31} bytes, depending on the specific Segment. A 64-bit Segment is part of the 64-bit Address Space and is no larger than 2^{62} bytes, but may be smaller on an implementation-dependent basis. The symbol *SEGBITS* is used to represent the actual number of bits implemented in each 64-bit Segment. So, if 40 virtual address bits are implemented, the actual size of the Segment is $2^{SEGBITS} = 2^{40}$ bytes. Software can determine the value of SEGBITS by writing all ones to the *EntryHi* register, then

reading the value back. Bits read as “1” from the VPN2 field allow software to determine the boundary between the VPN2 and Fill fields to calculate the value of SEGBITS.

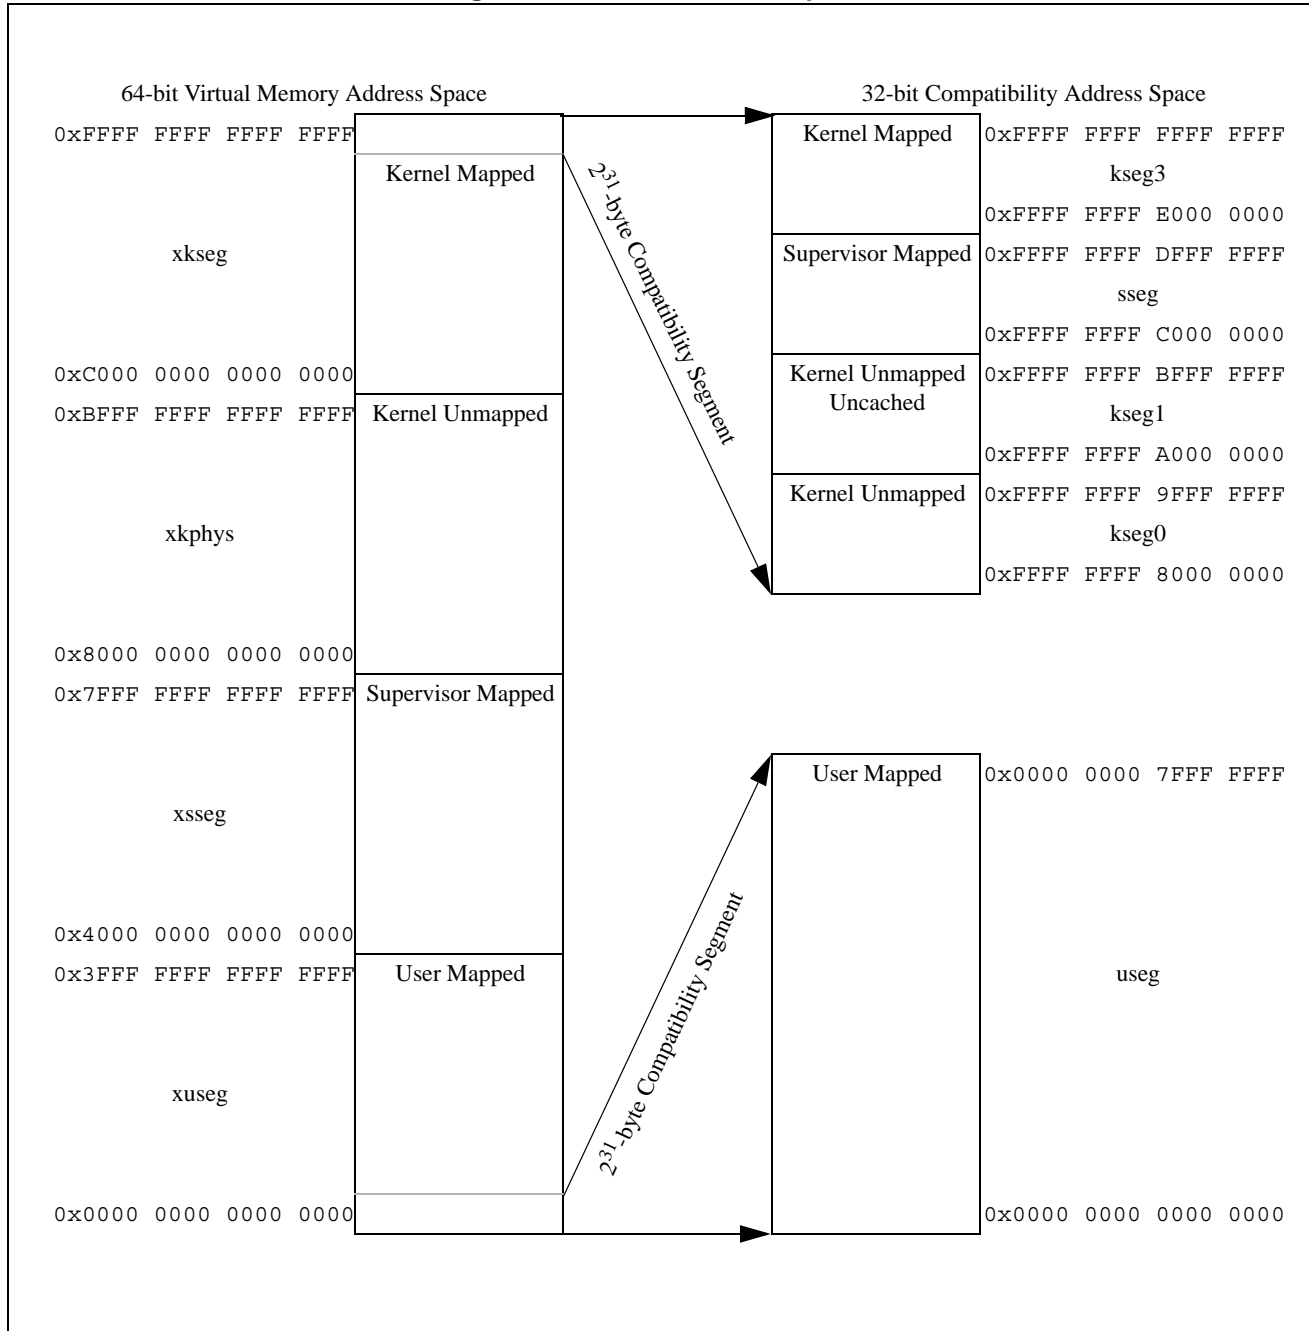

4.2.3 Physical Address Size (PABITS)

The number of physical address bits implemented is represented by the symbol *PABITS*. As such, if 36 physical address bits were implemented, the size of the physical address space would be $2^{PABITS} = 2^{36}$ bytes. The format of the *EntryLo0* and *EntryLo1* registers implicitly limits the physical address size to 2^{36} bytes. Software can determine the value of PABITS by writing all ones to the *EntryLo0* or *EntryLo1* registers, then reading the value back. Bits read as “1” from the *PFN* field allow software to determine the boundary between the *PFN* and *Fill* fields to calculate the value of PABITS.

4.3 Virtual Address Spaces

With support for 64-bit operations and address calculation, the MIPS64/microMIPS64 architecture implicitly defines, and provides support for, a 64-bit virtual Address Space; this is sub-divided into four Segments selected by bits 63..62 of the virtual address. To provide compatibility for 32-bit programs and MIPS32/microMIPS32 processors, a 2^{32} -byte Compatibility Address Space is defined, separated into two non-contiguous ranges in which the upper 32 bits of the 64-bit address are the sign extension of bit 31. The Compatibility Address Space is sub-divided similarly into Segments selected by bits 31..29 of the virtual address. [Figure 4.1](#) shows the layout of the Address Spaces, including the Compatibility Address Space and the segmentation of each Address Space.

Figure 4.1 Virtual Address Space.

Each Segment of an Address Space is classified as “Mapped” or “Unmapped”. A “Mapped” address is translated through the TLB or other address translation unit. An “Unmapped” address is not translated through the TLB and provides a window into the lowest portion of the physical address space, starting at physical address zero, and with a size corresponding to the size of the unmapped Segment.

The kseg1 Segment is classified as “Uncached”. References to this Segment bypass all levels of the cache hierarchy and allow direct access to memory without interference from the caches.

Table 4.1 lists the same information in tabular form.

Table 4.1 Virtual Memory Address Spaces

VA _{63..62}	Segment Name(s)	Maximum Address Range	Associated with Mode	Reference Legal from Mode(s)	Actual Segment Size	64-bit Address Enable	Segment Type
0b11	kseg3	0xFFFF FFFF FFFF FFFF through 0xFFFF FFFF E000 0000	Kernel	Kernel	2^{29} bytes	Always	32-bit Compatible
	sseg ksseg	0xFFFF FFFF DFFF FFFF through 0xFFFF FFFF C000 0000	Supervisor	Supervisor Kernel	2^{29} bytes	Always	32-bit Compatible
	kseg1	0xFFFF FFFF BFFF FFFF through 0xFFFF FFFF A000 0000	Kernel	Kernel	2^{29} bytes	Always	32-bit Compatible
	kseg0	0xFFFF FFFF 9FFF FFFF through 0xFFFF FFFF 8000 0000	Kernel	Kernel	2^{29} bytes	Always	32-bit Compatible
	xkseg	0xFFFF FFFF 7FFF FFFF through 0xC000 0000 0000 0000	Kernel	Kernel	$(2^{SEGBITS} - 2^{31})$ bytes ¹	KX	64-bit
0b10	xkphys	0xBFFF FFFF FFFF FFFF through 0x8000 0000 0000 0000	Kernel	Kernel	$8 \cdot 2^{PABITS}$ byte ¹ regions within the 2^{62} byte Segment	KX	64-bit
0b01	xsseg xksseg	0x7FFF FFFF FFFF FFFF through 0x4000 0000 0000 0000	Supervisor	Supervisor Kernel	$2^{SEGBITS}$ bytes ¹	SX	64-bit
0b00	xuseg xsuseg xkuseg	0x3FFF FFFF FFFF FFFF through 0x0000 0000 8000 0000	User	User Supervisor Kernel	$(2^{SEGBITS} - 2^{31})$ bytes ¹	UX	64-bit
	useg suseg kuseg	0x0000 0000 7FFF FFFF through 0x0000 0000 0000 0000	User	User Supervisor Kernel	2^{31} bytes	Always	32-bit Compatible

1. See 4.2.2 “Segment and Segment Size (SEGBITS)” and 4.2.3 “Physical Address Size (PABITS)” for an explanation of the symbols *SEGBITS* and *PABITS*, respectively.

Each Segment of an Address Space is associated with one of the three processor operating modes (User, Supervisor, or Kernel). A Segment associated with a mode is accessible if the processor is running in that or a more privileged mode. For example, a Segment associated with User Mode is accessible when the processor is running in User, Supervisor, or Kernel Modes. A Segment is not accessible if the processor is running in a less privileged mode than that associated with the Segment. For example, a Segment associated with Supervisor Mode is not accessible when the processor is running in User Mode, and such a reference results in an Address Error Exception. The “Reference Legal from Mode(s)” column in Table 4-2 lists the modes from which each Segment can be referenced legally.

If a Segment has more than one name, each name denotes the mode from which the Segment is referenced. For example, the Segment name “useg” denotes a reference from user mode, while the Segment name “kuseg” denotes a reference to the same Segment from kernel mode.

References to 64-bit Segments (as shown in the “Segment Type” column of [Table 4.1](#)) are enabled only if the appropriate 64-bit Address Enable is on (see [Section 3.5.1 on page 24](#), and the “64-bit Enable” column of [Table 4.1](#)). References to 32-bit Compatible Segments are always enabled.

4.4 Compliance

A MIPS64/microMIPS64 compliant processor must implement the following 32-bit Compatibility Segments:

- useg/kuseg
- kseg0
- kseg1

A MIPS64/microMIPS64-compliant processor using TLB-based address translation also must implement the kseg3 32-bit Compatible Segment.

4.5 Access Control as a Function of Address and Operating Mode

[Table 4.2](#) lists the action taken by the processor for each section of the 64-bit Address Space as a function of the processor’s operating mode. The selection of TLB Refill vector and other special behavior is listed for each reference.

Table 4.2 Address Space Access and TLB Refill Selection as a Function of Operating Mode

Virtual Address Range		Segment Name(s)	Action when Referenced from Operating Mode		
Symbolic	Assuming <i>SEGBITS</i> = 40, <i>PABITS</i> = 36		User Mode ¹	Supervisor Mode	Kernel Mode
0xFFFF FFFF FFFF FFFF through 0xFFFF FFFF E000 0000	0xFFFF FFFF FFFF FFFF through 0xFFFF FFFF E000 0000	kseg3	Address Error	Address Error	Mapped Refill Vector: TLB (KX=0) XTLB(KX=1). See Section 4.9 for special behavior when Debug _{DM} = 1.
0xFFFF FFFF DFFF FFFF through 0xFFFF FFFF C000 0000	0xFFFF FFFF DFFF FFFF through 0xFFFF FFFF C000 0000	sseg ksseg	Address Error	Mapped Refill Vector ² : TLB (KX=0) XTLB(KX=1).	Mapped Refill Vector ² : TLB (KX=0) XTLB(KX=1).

See Section 4.8 for implementation dependent behavior when Status _{ERL} =1.
$0x0000\ 0000\ 7FFF\ FFFF$ through $0x0000\ 0000\ 0000\ 0000$	$0x0000\ 0000\ 7FFF\ FFFF$ through $0x0000\ 0000\ 0000\ 0000$	useg suseg kuseg	Mapped Refill Vector: TLB (UX=0) XTLB(UX=1).	Mapped Refill Vector: TLB (UX=0) XTLB(UX=1).	Unmapped if Status _{ERL} =1. See Section 4.8 . Mapped if Status _{ERL} =0. Refill Vector: TLB (UX=0) XTLB(UX=1).

1. See [Section 4.10](#) for the special treatment of the address for data references when the processor is running in User Mode and the UX bit is zero.

2. Note that the Refill Vector for references to sseg/ksseg is determined by the state of the KX bit, not the SX bit.

4.6 Address Translation and Cacheability and Coherency Attributes for the kseg0 and kseg1 Segments

The kseg0 and kseg1 Unmapped Segments provide a window into the least significant 2^{29} bytes of physical memory; these are not translated using the TLB or other address translation unit. The cacheability and coherency attribute of the kseg0 Segment is supplied by the K0 field of the CP0 *Config* register. The cacheability and coherency attribute for the kseg1 Segment is always Uncached. [Table 4.3](#) describes how this transformation is done, as well as the source of the cacheability and coherency attributes for each Segment.

Table 4.3 Address Translation, Cacheability and Coherency Attributes for the kseg0 and kseg1 Segments

Segment Name	Virtual Address Range	Generates Physical Address	Cache Attribute
kseg1	$0xFFFF\ FFFF\ BFFF\ FFFF$ through $0xFFFF\ FFFF\ A000\ 0000$	$0x0000\ 0000\ 1FFF\ FFFF$ through $0x0000\ 0000\ 0000\ 0000$	Uncached

Table 4.3 Address Translation, Cacheability and Coherency Attributes for the kseg0 and kseg1 Segments

Segment Name	Virtual Address Range	Generates Physical Address	Cache Attribute
kseg0	0xFFFF FFFF 9FFF FFFF through 0xFFFF FFFF 8000 0000	0x0000 0000 1FFF FFFF through 0x0000 0000 0000 0000	From K0 field of <i>Config</i> Register.

4.7 Address Translation and Cacheability-and-Coherency Attributes for the xkphys Segment

The xkphys Unmapped Segment comprises eight address ranges, each of which provides a window into the entire 2^{PABITS} bytes of physical memory; as such, it is not translated using the TLB or other address translation unit. For this Segment, the cacheability and coherency attribute is taken from $VA_{61..59}$ and has the same encoding as that shown in [Table 9.11](#). An Address Error Exception occurs if $VA_{58..PABITS}$ are non-zero. If no Address Error Exception occurs, the physical address is taken from the $VA_{PABITS-1..0}$ virtual address field. [Table 4.4](#) shows the interpretation of the various fields of the virtual address when referencing the xkphys Segment.

Figure 4.2 Address Interpretation for the xkphys Segment

63 62 61	59 58	PABITS	PABITS-1	0
10	CCA	Address Error if Non-Zero	Physical Address	

Table 4.4 Address Translation and Cacheability Attributes for the xkphys Segment

Virtual Address Range		Generates Physical Address	Cache Attribute

0x8000 0000 0000 0000 + $2^{PABITS} - 1$ through 0x8000 0000 0000 0000	0x8000 000F FFFF FFFF through 0x8000 0000 0000 0000	0x0000 0000 0000 0000 + $2^{PABITS} - 1$ through 0x0000 0000 0000 0000	Uses encoding 0 of Table 9.11.

4.8 Address Translation for the kuseg Segment when Status_{ERL} = 1

To support the cache error handler, the kuseg Segment becomes an unmapped, uncached Segment, similar to the kseg1 Segment, if the *ERL* bit is set in the *Status* register. This allows the cache error exception code to operate uncached using GPR R0 as a base register to save other GPRs before use.

4.9 Special Behavior for the kseg3 Segment when Debug_{DM} = 1

If EJTAG is implemented on the processor, the EJTAG block must treat the virtual address range 0xFFFF FFFF FF20 0000 through 0xFFFF FFFF FF3F FFFF, inclusive, as a special memory-mapped region in Debug Mode. A MIPS64/microMIPS64 compliant implementation that also implements EJTAG must:

- explicitly range-check the address range as given, and not assume that the entire region between 0xFFFF FFFF FF20 0000 and 0xFFFF FFFF FFFF FFFF is included in the special memory-mapped region.
- enable the special EJTAG mapping for this region only in EJTAG Debug mode.

Even in Debug mode, normal memory rules can apply in some cases. See the EJTAG specification for details on this mapping.

4.10 Special Behavior for Data References in User Mode with Status_{UX} = 0

When the processor is running in User Mode, legal addresses have VA₃₁ equal zero, and the 32-bit virtual address is sign-extended (really zero-extended, because VA₃₁ is zero) into a full 64-bit address. This does not mean the normal address bounds checks on the sign-extended 64-bit address are sufficient. Unfortunately, there are cases in which a program running on a 32-bit processor can generate a data address that is legal in 32 bits, but which is not appropriately sign-extended into 64-bits. For example:

```
la r10, 0x80000000
lw r10, -4(r10)
```

The results of executing this address calculation on 32-bit and 64-bit processors with UX = 0 is shown below:

32-bit Processor	64-bit Processor
0x8000 0000	0xFFFF FFFF 8000 0000
+0xFFFF FFFC	+0xFFFF FFFF FFFF FFFC
0x7FFF FFFC	0xFFFF FFFF 7FFF FFFC

On a 32-bit processor, the result of this address calculation results in a valid useg address. However, on a 64-bit processor the sign-extended address in the base register is added to the sign-extended displacement as a 64-bit quantity. This results in a carry-out of bit 31, producing an address that is not properly sign-extended.

To provide backward compatibility with 32-bit User Mode code, MIPS64 compliant processors must implement the following special case for data references (and explicitly *not* for instruction references) when the processor is running in User Mode and the UX bit is zero in the *Status* register.

The effective address calculated by a load, store, or prefetch instruction must be sign-extended from bit 31 into bits 63..32 of the full 64-bit address, ignoring the previous contents of bits 63..32 of the address, before the final address is checked for address error exceptions or used to access the TLB or cache. This special-case is not done for instruction references.

This results in a properly zero-extended address for all legal data addresses. In the example given above, it cleans up the address. This results in a properly sign-extended address for all illegal data addresses (those in which bit 31 is a one). Code running in Debug Mode, Kernel Mode, or Supervisor Mode with the appropriate 64-bit address enable off

is prohibited from generating an effective address in which there is a carry-out of bit 31. If such an address is produced, the operation of the instruction generating such an address is **UNPREDICTABLE**.

4.11 32-bit Compatibility Addressing for Release 5 EVA, and Release 6

Section 4.10 “Special Behavior for Data References in User Mode with $Status_{UX} = 0$ ” applies to all architectural releases prior to Release 5, and Release 5 without Enhanced Virtual Addressing (EVA), where user mode data addresses are sign-extended only when $Status_{UX}=0$. In Release 6, or Release 5 implementations that support EVA, the same sign-extension applies to all modes (Kernel/Supervisor/User) and both data and instruction addresses. Release 5 implementations with no support for Enhanced Virtual Addressing default to the behavior described in Section 4.10.

Release 5 extensions of $Status_{KX/SX/UX}$ describe the new behavior. See CP0 *Status* definition for further detail.

The example in Section 4.10 “Special Behavior for Data References in User Mode with $Status_{UX} = 0$ ” is also applicable to Release 5 with EVA except that the 32-bit base address of `0x8000_0000` may be a *legal* address. This is because the MIPS32 User Segment can exceed 2GB (from Release 5 onwards), which means a legal base address above 2GB can be generated by user software. The User Segment may be extended by virtue of “*Enhanced Virtual Addressing (EVA)*”, a MIPS32 feature introduced in Release 5. In this example, the resultant 64-bit address is correctly placed in the lower 2GB 32-bit compatible virtual address range as a result of canonical sign-extension. Canonical sign-extension is the generation of a 64-bit address by sign-extension from bit 31.

All Release 6 implementations must support the new addressing extensions for 32-bit compatibility.

For all implementations supporting this behavior, the canonical check is performed on the input operands of the effective address generation. The check is to prevent the accidental aliasing of non-canonical input addresses to a canonical effective address, which can happen if, for example, kernel software uses a 64-bit instruction when $Status_{KX}=0$. Kernel mode can always execute 64-bit instructions. If the input is non-canonical, then an Address Error must be signaled, either by the addressing instruction itself, or at the target of a control flow instruction. The Address Error exception is able to be taken at the target itself because the canonical error is propagated to the target address after address generation. The only exception for the control-flow case is Release 6 Jump Immediates (JIC/JIALC), where it is possible for the non-canonical base to be added to a sign-extended immediate and create a canonical address, which means the Address Error is undetected. This conversion of non-canonical to canonical happens if the resultant address crosses the boundary between the 32-bit compatibility regions - software must avoid such cases.

The canonical sign-extension check of inputs could apply to up to 2 inputs of address generation in Release 5 or prior, which support indexed memory references. In Release 6, the check is limited to a single input as indexed addressing has been eliminated.

The addressing extensions for 32-bit compatibility apply to :

- An instruction fetch address.
- An instruction such as a Load/Store, LL/SC, LLD/SCD, CACHE, PREF, SYNCI (and EVA extensions such as LWL). These instructions are generically referred to as DMEMREF in the pseudo-code below.
- PC-relative instructions : Branch, Release 6 ADDIUPC, ALUIPC, AUIPC, LWPC, LWUPC, LDPC.
- PC-region instructions : Jump, Jump and Link, Jump and Link Exchange
- Control-transfer Jump Register instructions.
- Hardware Page Table Walker address generation.

Virtual Memory

Instruction fetch and Hardware Page Table Walker address generation includes speculative non-instruction based addressing to which the 32-bit compatibility rules also apply. For speculative instruction fetch the rules for addressing due to sequential fetch and control-flow changes are identical to the rules for control flow instruction execution : the fetch PC must be checked for Address Error, and in its absence, the PC is sign-extended.

Branch instructions and PC-relative Release 6 ADDIUPC, ALUIPC, AUIPC, LWPC, LWPUPC, LDPC do not require canonical checks of the inputs to address generation, as the PC itself is typically always canonically compliant. However, it is required that the function `effective_address()` applies to such instructions. PC-Region Jumps also fall into the same category of PC-relative instructions.

Software may errantly cause the PC to be canonically non-compliant by writing an inappropriate value to CP0 *EPC*, or writing a value to *Status_{KX/SX/UX}* that is incompatible with the current state of PC. For the latter case, software must execute an instruction hazard barrier (e.g., JALR.HB) after the MTC0 that changes *Status_{KX/SX/UX}* so the change takes effect no later than the target of the hazard barrier. Application of `effective_address()` will take care of the former case.

The pseudo-code for `effective_address` describes the new scheme for effective address generation for 32-bit compatible addressing. The pseudo-code is applied specifically to instruction and data addressing instructions. It can be applied to all mentioned instructions in Release 5 and Release 6, as the pseudo-code excludes instructions in Release 5 if Enhanced Virtual Addressing is not supported.

```
function effective_address(base, offset)

    EffKSU = EffKSU()

    // Release 6 (always) or EVA present (Release 5)
    if ( ConfigAR >= 2 or (ConfigAR=1 and Config5EVA=1))
        // 32-bit Compatible Addressing?
        if ( (EffKSU=0b00 and Status.KX=0)
            or (EffKSU=0b01 and Status.SX=0)
            or (EffKSU=0b02 and Status.UX=0) )
            if ( canonical_error(base) or
                ((ConfigAR=1 and decode(INDEXED DMEMREF)) and canonical_error(offset)) )
                // Indexed DMEMREF only applies pre-Release 6
                // No sign-extension when base or offset is not canonical.
                // An address error may occur later on when ea is translated by MMU.
                ea = base + offset
                // data memory insts (eg load/store) cause Address Error
                // Other addressing instructions take error at target.
                if (decode(DMEMREF))
                    SignalException(AddressError)
                endif
            else
                ea = sign_extend(base + offset)
            endif
        else // 64-bit Addressing
            ea = base + offset
        endif
    elseif

        // Not Release 6 and not EVA
```

```

    // pre-Release 5 special user handling with UX=0...
    if ( EffKSU=0b10 and StatusUX=0 and decode(DMEMREF) )
        ea = sign_extend(base + offset)
    else
        ea = base + offset
    endif
endif

// Effective KSU
sub EffKSU
    if (decode(EVA DMEMREF))
        return 0b10
    elseif ( DebugDM=1 or StatusEXL=1 or StatusEXL=1)
        return 0b00
    else
        return StatusKSU
    endif
endsub

// Determine whether 64-bit value is sign-extended from bit 31.
sub canonical_error (addr)
    input addr
    if ( ((addr[31] = 1) and (addr[63:32] != 0xFFFFFFFF)) or
        ((addr[31] = 0) and (addr[63:32] != 0x0)) )
        return true
    else
        return false
    endif
endsub

// Determine whether instruction opcode is of specific type.
sub decode(itype)
    input itype
    if (opcode=itype)
        return true
    else
        return false
    endif
endsub

// Sign extend from bit 31
sub sign_extend(data)
    input data
    return {{32{data[31]}},data[31:0]}
endsub

endfunction

```

4.11.1 Use Cases for Effective_Address Generation Function

The function `effective_address()` is to be used by specific instructions classes in the manner described below.

- Data Memory Reference (Load/Store/Cache/Prefetch/Load-Linked/Store-Conditional/SyncI)

`effective_address(GPR[index],offset)`

- Indexed Data Memory Reference (pre-Release 6 Indexed Load/Store/Prefetch)
`effective_address(GPR[index],GPR[index])`
- Jump Register with no Immediate
`effective_address(GPR[index],0)`
- Jump Register with Immediate (Release 6 JIC/JIALC)
`effective_address(GPR[index],offset)`
- PC-Relative (Branch/ADDIUPC/ALUIPC/AUIPC/LWPC/LWUPC/LDPC)
`effective_address(PC,offset)`
- PC-Region (J/JAL/JALX)
`effective_address(PC,immediate)`

4.12 TLB-Based Virtual Address Translation¹

This section describes the TLB-based virtual address translation mechanism. Sufficient TLB entries must be implemented to avoid a TLB exception loop on load and store instructions.

4.12.1 Address Space Identifiers (ASID)

The TLB-based translation mechanism supports Address Space Identifiers to uniquely identify the same virtual address across different processes. The operating system assigns ASIDs to each process, and the TLB keeps track of each ASID during address translation. In certain circumstances, the operating system may want to associate the same virtual address with all processes; for this, the TLB includes a global (G) bit which over-rides the ASID comparison during translation.

4.12.2 TLB Organization

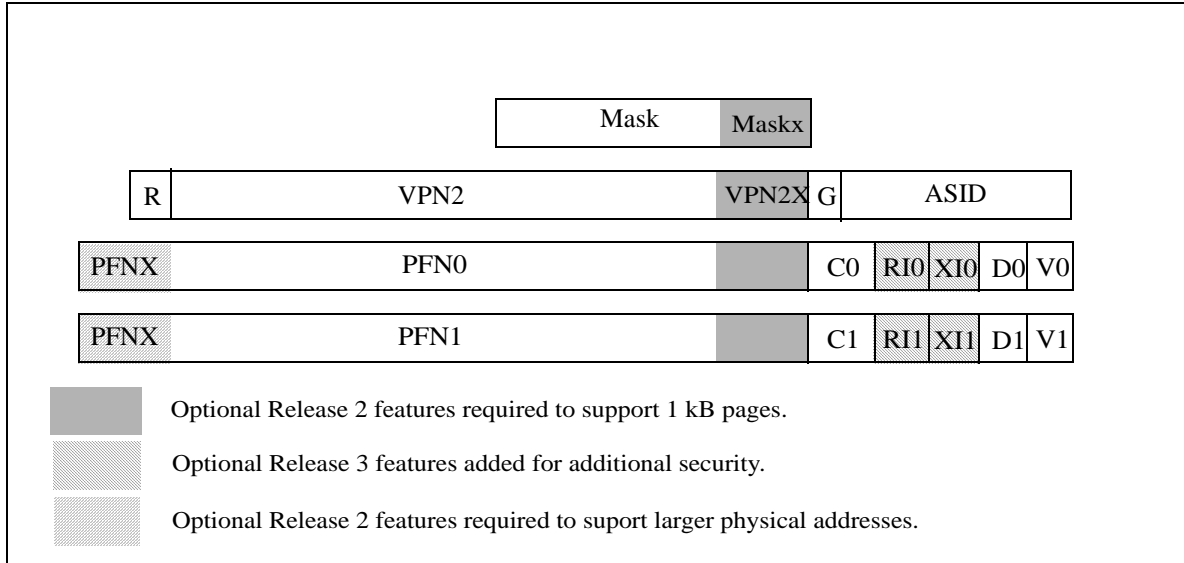

The TLB is a fully-associative structure for translating virtual addresses. Each entry contains two logical components: a comparison section, and a physical translation section. The comparison section includes the mapping region specifier (R) and the virtual page number (VPN2 and, in Release 2 and subsequent releases, VPNX, which is the virtual page number/2 since each entry maps two physical pages) of the entry, the ASID, the G(lobal) bit, and a recommended mask field that allows mapping different page sizes with a single entry. The physical translation section contains a pair of entries, each of which contains the physical page frame number (PFN, and in Release 2 and subsequent releases, PFNX), a valid (V) bit, a dirty (D) bit, optionally read-inhibit and execute-inhibit (RI & XI) bits, and a cache coherency field (C) for which the valid encodings are given in [Table 9.11](#). There are two entries in the translation section for each TLB entry because each TLB entry maps an aligned pair of virtual pages, and the pair of physical translation entries corresponds to the even and odd pages of the pair.

1. See [A.1 “Fixed Mapping MMU” on page 347](#) and [A.2 “Block Address Translation” on page 351](#) for descriptions of alternative MMU organizations.

In Revision 3 of the architecture, the RI and XI bits were added to the TLB to enable more secure access of memory pages. These bits (along with the Dirty bit) allow the implementation of read-only, write-only, and no-execute access policies for mapped pages.

Figure 4.3 shows the logical arrangement of a TLB entry, including the optional support added in Release 2 of the Architecture for 1 kB page sizes and the increase in physical address size from the 36-bit limit in Release 1. Light grey fields denote extensions to the right that are required to support 1 kB page sizes. Medium grey fields denote extensions to the left that are required to support larger physical addresses. Neither set of extensions is present in an implementation of Release 1 of the Architecture.

Figure 4.3 Contents of a TLB Entry

The fields of the TLB entry correspond exactly to the fields in the CP0 *PageMask*, *EntryHi*, *EntryLo0*, and *EntryLo1* registers. The even page entries in the TLB (such as PFN0) come from *EntryLo0*. Similarly, odd page entries come from *EntryLo1*.

4.12.3 TLB Initialization

In many processor implementations, software must initialize the TLB during the power-up process. In processors that detect multiple TLB matches, and signal this through a machine-check assumption, software must be able to handle such an exception or use a TLB initialization algorithm that minimizes, or eliminates, the possibility of the exception.

In Release 1 of the Architecture, processor implementations can detect and report multiple TLB matches either on a TLB write (TLBWI or TLBWR instructions) or a TLB read (TLB access or TLBR or TLBP instructions). In Release 2 (and subsequent releases) of the Architecture, processor implementations are limited to reporting multiple TLB matches only on a TLB write; this is also true of most implementations of Release 1 of the Architecture.

The following code example shows a TLB initialization routine that, on implementations of Release 2 (and subsequent releases) of the Architecture, eliminates the possibility of reporting a machine check during TLB initialization. This example has an equivalent effect on implementations of Release 1 of the Architecture that report multiple TLB

exceptions only on a TLB write and minimizes the probability of such an exception on other implementations. The following example is for processors that do not implement TLB invalidate instructions, that is: *Config4_{IE}=0x0*.

```

/*
 * InitTLB
 *
 * Initialize the TLB to a power-up state, guaranteeing that all entries
 * are unique and invalid.
 *
 * Arguments:
 *   a0      = Maximum TLB index (from MMUSize field of C0_Config1)
 *
 * Returns:
 *   No value
 *
 * Restrictions:
 *   This routine must be called in unmapped space
 *
 * Algorithm:
 *   va = kseg0_base;
 *   for (entry = max_TLB_index; entry >= 0, entry--) {
 *       while (TLB_Probe_Hit(va)) {
 *           va += Page_Size;
 *       }
 *       TLB_Write(entry, va, 0, 0, 0);
 *   }
 *
 * Notes:
 *   - The Hazard macros used in the code below expand to the appropriate
 *     number of SSNOPs in an implementation of Release 1 of the
 *     Architecture, and to an ehb in an implementation of Release 2 of
 *     the Architecture. See , "CP0 Hazards," on page 121 for
 *     more additional information.
 */

InitTLB:
/*
 * Clear PageMask, EntryLo0 and EntryLo1 so that valid bits are off, PFN values
 * are zero, and the default page size is used.
 */
    dmtc0 zero, C0_EntryLo0      /* Clear out PFN and valid bits */
    dmtc0 zero, C0_EntryLo1
    dmtc0 zero, C0_PageMask      /* Clear out mask register */
/* Start with the base address of kseg0 for the VA part of the TLB */
    la      t0, A_K0BASE         /* A_K0BASE == 0xFFFF.FFFF.8000.0000 */

/*
 * Write the VA candidate to EntryHi and probe the TLB to see if it is
 * already there. If it is, a write to the TLB may cause a machine
 * check, so just increment the VA candidate by one page and try again.
 */
10:
    dmtc0 t0, C0_EntryHi         /* Write VA candidate */
    TLBP_Write_Hazard()          /* Clear EntryHi hazard (ssnop/ehb in R1/2) */
    tlbp                         /* Probe the TLB to check for a match */
    TLBP_Read_Hazard()           /* Clear Index hazard (ssnop/ehb in R1/2) */
    mfc0 t1, C0_Index            /* Read back flag to check for match */
    bgez t1, 10b                /* Branch if about to duplicate an entry */

```

```

        daddiu t0, (1<<S_EntryHiVPN2)      /* Add 1 to VPN index in va */

/*
 * A write of the VPN candidate will be unique, so write this entry
 * into the next index, decrement the index, and continue until the
 * index goes negative (thereby writing all TLB entries)
 */
        mtc0    a0, C0_Index                /* Use this as next TLB index */
        TLBW_Write_Hazard()                /* Clear Index hazard (ssnop/ehb in R1/2) */
        tlbwi                                /* Write the TLB entry */
        bne     a0, zero, 10b                /* Branch if more TLB entries to do */
        addiu   a0, -1                      /* Decrement the TLB index

/*
 * Clear Index and EntryHi simply to leave the state constant for all
 * returns
 */
        mtc0    zero, C0_Index
        dmtc0   zero, C0_EntryHi
        jr      ra                          /* Return to caller */
        nop

```

In the code above, 64-bit operations are shown for operations with the TLB. For MIPS64 processors running 32-bit software, these instructions can be changed to the corresponding 32-bit instructions.

The V(alid) bit within the TLB entry indicates if the Page Table Entry held in the TLB entry is valid. This Valid bit does not indicate if the TLB entry has been initialized.

The above initialization routine relies on using unmapped addresses to be written to the VPN2 field of the TLB entry to create entries that never match on mapped addresses. When Segmentation Control is implemented (*Config3_{SC}*=1), the virtual address map can be programmed to not have any unmapped address regions. For this reason, the above routine cannot be used when Segmentation Control is implemented. Instead, use the TLB invalidate feature. The TLB invalidate feature is discussed in the next paragraph.

Release 3 introduces another optional valid bit that denotes whether the virtual address (the VPN2 field) of the TLB entry has been initialized or not. If the *VPN2* field is marked as invalid, the entry is ignored on address match for memory accesses. This additional valid bit is visible through the EHINV field of the *EntryHi* register. If this bit is implemented (indicated by *Config4_{IE}*), there are three ways to initialize a TLB entry: the TLBINV, TLBINVF, and TLBWI instructions. This feature is required if Segmentation Control is implemented and is required for FTLB/VTLB MMUs; otherwise, it is optional.

For Release 3 processors that implement TLB invalidate instructions, the code to initialize the TLB is much simpler: just write each TLB entry with the *EntryHi_{EHINV}* bit set.

```

/*
 * InitTLB
 *
 * Initialize the TLB to a power-up state, guaranteeing that all entries
 * are unique and invalid.
 *
 * Arguments:
 *   a0      =   Maximum TLB index (from MMUSize field of C0_Config1)
 *
 * Returns:
 *   No value
 */

```

Virtual Memory

```
* Restrictions:
*   This routine must be called in unmapped space
* Algorithm:
*   Write Each TLB entry with EntryHi.EHINV=1
*
* Notes:
*   - The Hazard macros used in the code below expand to the appropriate
*     number of SSNOPs in an implementation of Release 1 of the
*     Architecture, and to an ehb in an implementation of Release 2 of
*     the Architecture. See , "CP0 Hazards," on page 121 for
*     more additional information.
*/

InitTLB:

/*
* Clear PageMask, EntryLo0 and EntryLo1 so that valid bits are off, PFN values
* are zero, and the default page size is used.
*/
    dmtc0    zero, C0_EntryLo0          /* Clear out PFN and valid bits */
    dmtc0    zero, C0_EntryLo1
    mtc0     zero, C0_PageMask          /* Clear out mask register */
    ori      t0, zero, 0x400
    dmtc0    t0, C0_EntryHi            /* Set EHINV bit, Clear VPN2 field */
10:
    mtc0     a0, C0_Index              /* Use this as next TLB index */
    TLBW_Write_Hazard()               /* Clear Index hazard (ssnop/ehb in R1/2) */
    tlbwi                                         /* Write the TLB entry */
    bne      a0, zero, 10b             /* Branch if more TLB entries to do */
    addiu    a0, -1                    /* Decrement the TLB index
*/
* Clear Index and EntryHi simply to leave the state constant for all
* returns
*/
    mtc0     zero, C0_Index
    dmtc0    zero, C0_EntryHi
    jr       ra                        /* Return to caller */
    nop
```

4.12.4 Address Translation

Release 2 of the Architecture introduced support for 1 kB pages, and larger physical addresses. For clarity in the discussion below, take the following terms in the general sense to include the new Release 2 features:

Term Used Below	Release 2 Substitution	Comment
VPN2	VPN2 VPN2X	Release 2 (and subsequent releases) implementations that support 1 kB pages concatenate the VPN2 and VPN2X fields to form the virtual page number for a 1 kB page.

Term Used Below	Release 2 Substitution	Comment
PFN	PFNX PFN	Release 2 (and subsequent releases) implementations that support larger physical addresses concatenate the PFNX and PFN fields to form the physical page number.
Mask	Mask MaskX	Release 2 (and subsequent releases) implementations that support 1 kB pages concatenate the Mask and MaskX fields to form the don't care mask for 1 kB pages.

When an address translation is requested, the virtual page number and the current process ASID are presented to the TLB. All entries are checked simultaneously for a match, which occurs when all of the following conditions are true:

- The current process ASID (as obtained from the *EntryHi* register) matches the ASID field in the TLB entry, or the G bit is set in the TLB entry.
- Bits 63..62 of the virtual address match the region code in the R field of the TLB entry.
- The appropriate bits of the virtual page number match the corresponding bits of the VPN2 field stored within the TLB entry. The “appropriate” number of bits is determined by the Mask fields in each entry by ignoring each bit in the virtual page number and the TLB VPN2 field corresponding to those bits that are set in the Mask fields. This lets each entry of the TLB support a different page size, as determined by the *PageMask* register at the time that the TLB entry was written. If the recommended *PageMask* register is not implemented, the TLB operation is as if the *PageMask* register had been written with the encoding for a 4 kB page.

If a TLB entry matches the address and ASID presented, the corresponding PFN, C, V, and D bits (and optionally RI and XI bits) are read from the translation section of the TLB entry. Which of the two PFN entries is read is a function of the virtual address bit immediately to the right of the section masked with the Mask entry.

The valid and dirty bits (and optionally RI and XI bits) determine the final success of the translation. If the valid bit is off, the entry is not valid, and a TLB Invalid exception is raised. If the dirty bit is off and the reference was a store, a TLB Modified exception is raised. If there is an address match with a valid entry and no dirty exception, the PFN and the cache coherency bits are appended to the offset-within-page bits of the address to form the final physical address with attributes. If the RI bit is implemented and is set, and the reference was a load, a TLB Invalid (or TLBRI) exception is raised. If the XI bit is implemented and is set, and the reference was an instruction fetch, a TLB invalid (or TLBXI) exception is raised.

For clarity, the TLB lookup processes have been separated into two sets of pseudo code:

1. One used by an implementation of Release 1 of the Architecture, or an implementation of Release 2 (and subsequent releases) of the Architecture that does not include 1 kB page support (as denoted by *Config3_{SP}*). This instance is called the “4 kB TLB Lookup”.
2. One used by an implementation of Release 2 (and subsequent releases) of the Architecture that includes 1 kB page support. This instance is called the “1 kB TLB Lookup”.

The 4 kB TLB Lookup pseudo code is:

```

found ← 0
for i in 0...TLBEntries-1
    if (TLB[i]R = va63..62) and
        ((TLB[i]VPN2 and not (TLB[i]Mask)) = (vaSEGBITS-1..13 and not (TLB[i]Mask))) and
        (TLB[i]G or (TLB[i]ASID = EntryHiASID)) then

```

```

# EvenOddBit selects between even and odd halves of the TLB as a function of
# the page size in the matching TLB entry. Not all page sizes need
# be implemented on all processors, so the case below uses an 'x' to
# denote don't-care cases. The actual implementation would select
# the even-odd bit in a way that is compatible with the page sizes
# actually implemented.
case TLB[i]Mask

Table 4.5 demonstrates how the physical address is generated as a function of the page size of the TLB entry that matches the virtual address. The “Even/Odd Select” column of **Table 4.5** indicates which virtual address bit is used to select between the even (EntryLo0) or odd (EntryLo1) entry in the matching TLB entry. The “PA_{(PABITS-1)..0} Generated From” columns specify how the physical address is generated from the selected PFN and the offset-in-page bits in the virtual address. In this column, PFN is the physical page number as loaded into the TLB from the *EntryLo0* or *EntryLo1* registers, and has one of two bit ranges:

PFN Range	PA Range	Comment
$\text{PFN}_{(\text{PABITS}-1)-12..0}$	$\text{PA}_{\text{PABITS}-1..12}$	Release 1 implementation, or Release 2 (and subsequent releases) implementation without support for 1 kB pages
$\text{PFN}_{(\text{PABITS}-1)-10..0}$	$\text{PA}_{\text{PABITS}-1..10}$	Release 2 (and subsequent releases) implementation with support for 1 kB pages enabled

4.13 Segmentation Control

As an optional alternative to fixed memory segmentation, a programmable segmentation control feature has been added to Release 3. This improves the flexibility of the MIPS64 virtual address space.

In the traditional MIPS64 virtual address memory map, the mappability and cacheability attributes of segments are mostly fixed. For example, useg has its mappability attribute fixed while kseg0/1 have their cacheability and mappability attributes fixed. Segmentation Control replaces these fixed attributes with programmable controls for these attributes.

The Segmentation Control system can be used to implement a fully translated flat address space, or used to alter the relative size of cached and uncached windows into the physical address space.

The existence of the unmapped segments in the virtual address map prevents a MIPS CPU from being fully virtualized. Another use of Segmentation Control is to remove the unmapped segments from the virtual address map. Future support for CPU virtualization would require Segmentation Control.

With Segmentation Control, address translation begins by matching a virtual address to the region specified in a Segment Configuration. The virtual address space is therefore definable as the set of memory regions specified by Segment Configurations. The behavior and attributes of each region are also specified by Segment Configurations. Six Segment Configurations are defined, fully mapping the 32-bit Compatibility virtual address space.

If Segmentation Control is implemented, the Segment Configurations are always active. Coprocessor 0 registers *SegCtl0*, *SegCtl1*, and *SegCtl2* contain six Segment Configurations as well as various configuration fields. *Config5* contains additional control and configuration fields.

The attributes of a Segment Configuration are:

- Access permissions from user, kernel, and supervisor modes
- Enable mapping (address translation) using the MMU specified in *Config_{MT}*
- Physical address when mapping is disabled
- Cache attribute when mapping is disabled
- Force to unmapped, uncached when *Status_{ERL}*=1

Besides the segments controlled by *SegCtl** registers, the reset and BEV exceptions may use another segment which is active only in kernel mode. Please read [Section 4.13.1 "Exception Behavior under Segmentation Control"](#) for an explanation on how exceptions interact with programmable segmentation.

The MIPS64 xkphys memory is divided into 8 regions, these regions are configurable via the *SegCtl_{IXAM}* and the *SegCtl_{2XR}* register fields.

On reset, Segment Configuration default is implementation specific. A configuration backward compatible with MIPS64 legacy fixed segmentation is defined by [Table 9.30](#)

Segment configuration access control modes are specified in [Table 9.29](#)

When Segment Control is implemented (*Config3_{SC}* = 1), addressing control bits *Status_{KX}*, *Status_{SX}*, *Status_{UX}* remain active.

MIPS64 xkphys regions may be controlled via Segmentation Control. The xkphys memory regions are enabled by the *SegCtl2_{Xr}* field.

For enabled MIPS64 xkphys regions, the *KS*, *SX* and *UX* bits of *Status* are used together with the xkphys access control mode. The xkphys access control mode is set with the *SegCtl1_{XAM}* field.

The access control mode has an associated minimum privilege level ([Table 9.29](#)), KERNEL (AM = UK, MK or XKP), SUPERVISOR (AM = MSK) or USER (AM = MUSK, MUSUK or UUSK).

Access to xkphys regions with a minimum privilege level of KERNEL are allowed when the processor is operating with KERNEL privilege and the *Status_{KX}* bit is set.

Access to xkphys regions with a minimum privilege level of SUPERVISOR are allowed when the processor is operating with SUPERVISOR or KERNEL privilege and the *Status_{SX}* bit is set.

Access to xkphys regions with a minimum privilege level of USER are allowed when the processor is operating at any privilege level and the *Status_{UX}* bit is set.

Operation of MIPS64 Segmentation Control is described below:

```

/* Inputs
 * vAddr - Virtual Address
 * pLevel - Privilege level - USER, SUPER, KERNEL
 * IorD - Access type - INSTRUCTION or DATA
 * LorS - Access type - LOAD or STORE
 *
 * Outputs
 * mapped - segment is mapped
 * pAddr - physical address (valid when unmapped)
 * CCA - cache attribute (valid when unmapped)
 *
 * Exceptions: Address Error

See [Section 9.16 “SegCtl0 \(CP0 Register 5, Select 2\)”](#).

The presence of this facility is indicated by the SC field in the *Config3* register. See [Section 9.49 “Configuration Register 3 \(CP0 Register 16, Select 3\)”](#).

Debug mode behavior is retained in dseg.

4.13.1 Exception Behavior under Segmentation Control

4.13.1.1 Terminology

For this section discussing exception behavior under Segmentation Control, these terms are used:

Legacy Memory map - A MIPS64 Virtual/Physical memory system as described by [Section 4.3 on page 29](#).

Non-Reset Exceptions - exceptions which would use *EBase* for the vector location when *Status_{BEV}*=0

Overlay Segment - A memory segment with these properties:

- Totally managed by hardware, not software programmable.
- Intercepts memory requests before they are dealt with by the rest of the virtual memory system.
- Is active only in specific execution modes.

A pre-existing example of an overlay segment is DSEG which is part of the EJTAG debug architecture and is only active in DebugMode. and *ECR_{ProbeEn}*=1

4.13.1.2 Reset and BEV Vector Base Addresses under Segmentation Control

In the legacy memory map, the Reset/BEV vector base is fixed at virtual address 0xFFFF.FFFF.BFC0.0000 and physical address 0x0000.0000.1FC0.0000.

In contrast, Segmentation Control does not define a fixed value for the Reset/BEV vector base virtual address. Instead the virtual addresses and physical addresses for Reset/BEV vector base are considered implementation-specific. In Segmentation Control, the physical address of Reset/BEV vector does not have to be derived from the virtual address by dropping VA[31:29], other mappings are allowed.

Reset and BEV exceptions - Cacheability and Map-ability

In the legacy memory map, the memory accesses to the Reset/BEV vector region are within KSEG1, which ensures the accesses to this region are always uncached and unmapped.

The architecture requires that the reset and BEV exceptions vector to a memory region which is uncached and unmapped.

Solution 1 - Uncached and Unmapped Segment always available

This architecture requirement can be satisfied if the system can guarantee these conditions:

1. One of the segments always powers up as uncached and unmapped for kernel mode.
2. That segment is always kept as uncached and unmapped for kernel mode.
3. The reset and BEV vectors always reside in the above mentioned segment.

If these conditions are met, then no special support is needed for reset and BEV exceptions.

Solution 2 - Overlay Segments for Reset and BEV exceptions

Not all systems may want to maintain the conditions for Solution 1, since Segmentation Control allows for any of the segments to be programmed with any valid cache-ability and mappability attribute.

To meet the architecture requirement without reserving one segment as uncached and unmapped, overlay segments are introduced in Segmentation Control for reset and exceptions while in kernel mode.

These overlay segments allow the reset/BEV regions to be accessed without accessing the caches and TLB during reset and BEV exceptions. That is, when a reset or BEV exception is taken, the overlay segment handles the memory requests for that vector region and the overlay segment attributes over-rides the cacheability and mappability attributes of the regular segment control register.

If Solution 1 is not implemented, the CPU must implement at least one overlay segment for the Reset/BEV vector location. If there is only one overlay segment for the Reset/BEV vector location, it must deal with memory requests as uncached and unmapped.

Solution 2 - Requirements for Overlay Segments

The starting virtual address, starting physical address and size of this overlay segment are implementation-specific. The overlay segments must be naturally aligned both in the virtual address space as well as the physical address space. The physical address of the overlay segment does not have to be derived from the virtual address of the overlay by dropping VA[31:29], other mappings are allowed.

The overlay segment must be at least 2 kB in size. Implementations would likely choose much larger sizes for the overlay segment to access non-volatile memory and potentially other IO devices.

The overlay segment must be accessible while in kernel-mode (*Status_{ERL}*=1 or *Status_{ERL}*=1 or *Status_{KSU}*=kernel).

Solution 2 - Option A - Two Overlay Segments for KSEG0/1 legacy behavior

An implementation may optionally support a second overlay segment for the Reset/BEV vector physical address region. The purpose of two overlay segments is to mimic the cached and uncached views made available through KSEG0 and KSEG1 segments in the legacy memory system. After reset, one overlay segment would be given uncached and unmapped access to these vectors while the other overlay segment would give cached and unmapped access to the vectors.

The two overlay segments must meet these requirements:

- The two overlay segments are of the same size.
- The two overlay segments cannot overlap in the virtual address space.
- The two overlay segments must point to the same physical address space.
- Both overlay segments must treat memory accesses as unmapped.
- The overlay segment in which the BEV/Reset vector location resides must come out of reset treating memory accesses as uncached.
- The cache coherency of each overlay segment can be fixed by hardware or programmable through the legacy register fields in *Config* (see next section).

To mimic the legacy KSEG0/KSEG1 behaviors, one overlay segment would be located within the addresses which belong to *SEGCTL1_CFG3* (virtual addresses equivalent to legacy KSEG0 segment) and the other overlay segment would be located within the addresses which belong to *SEGCTL1_CFG2* (virtual addresses equivalent to legacy KSEG1 segment).

Solution 2 - Option B - Overlay Segments using legacy Coherency Control Register Fields

Segmentation Control allows the legacy *Config_K0*, *Config_K23* and *Config_KU* fields to control cacheability of their respective non-legacy segments coming out of reset. This is in effect when *Config5_K* = 0. If the overlay segment resides in one of these segments, it is optionally allowed for the overlay segment to get its cacheability attribute from the appropriate field (*K0*, *K23*, *KU*) within the *Config* register. If the BEV/Reset vector resides in a overlay segment which is controlled by that *Config* register field, then that register field must be set by hardware to uncached CCA value upon reset.

The use of these register fields allows the boot firmware to be run cached after the caches have been initialized. Code should not be executing within the overlay segment while the cache coherency of the overlay segment would be changing through writing the *Config* register field.

For example, if the Reset/BEV overlay segments resides within the segment controlled by *SEGCTL1_CFG3* (virtual addresses equivalent to legacy KSEG0 segment) and *Config_K0* is enabled coming out of reset, *Config_K0* must be reset to the uncached CCA value. When *Config_K0* is modified, code execution should not be within the *SEGCTL1_CFG3* segment.

NOTE: This use of these legacy coherency fields within the *Config* register is only meant for systems using legacy virtual address maps. For systems using non-legacy virtual address maps, the recommendation is to disable the legacy coherency fields within the *Config* register.

Solution 1 or Solution 2 - Option C - Relocation of non-Reset BEV exception vectors after Reset

There might be transitional devices in which the physical address map was inherited from legacy systems, but the virtual address map to be used is set up by programming the Segmentation Control registers. For such transitional devices, it might be useful to relocate the non-Reset BEV exceptions to an address more appropriate for the non-legacy virtual address map. Such capability is allowed by Segmentation Control.

The *Config5_K* bit can be used for this purpose. If *Config5_K* = 1, it is allowed to relocate the BEV vector base address for non-reset exceptions.

This feature would be used in this fashion:

1. Device boots up using legacy reset location (e.g. virtual address 0xFFFF.FFFF.BFC0.0000)
2. Segmentation Registers are programmed to new non-legacy address map.
3. BEV vector base moved to new location using this capability. Non-Reset BEV exceptions would now use this new location.

For the rest of this section, the following names are used:

- EffectiveBEV_VA - the virtual address of the reset/BEV vector

4.13.1.3 BEV Exceptions under Segmentation Control

As compared to a legacy system, the vector offsets are unchanged while the source of the vector base address is changed.

For Reset/Soft-Reset/NMI, the reset vector is located at virtual address (EffectiveBEV_VA).

If $Status_{BEV}=1$ during other exceptions, the vectors are located at virtual address (EffectiveBEV_VA + 0x200 + offset).

Requirements for Option 2 - Overlay Segments

If there is only one overlay segment for BEV/Reset, then the overlay segment deals with these memory requests as unmapped and uncached. The overlay segment is active in Kernel mode ($Debug_{DM}=0$ and ($Status_{KSU}=\text{Kernel}$ or $Status_{ERL}=1$ or $Status_{EXL}=1$)).

If implemented, the second overlay segment is active at the same time as the first BEV/Reset overlay segment. If there are two overlay segments, the one which contains the reset/BEV vector must use uncached and unmapped behavior coming out of reset. Both overlay segments must use unmapped coherency.

If $Config5_K=0$ and the overlay resides in a segment that is controlled by one of the $Config_{K0}$, $Config_{K23}$ and $Config_{KU}$ register fields, it is allowed for the appropriate $Config$ register field to control the cacheability attribute of the overlay segment.

4.13.1.4 Debug Exceptions under Segmentation Control

$ECR_{ProbTrap}=0$

As compared to a legacy system, the vector offset is unchanged while the source of the vector base address is changed.

The debug exception vector is located at (EffectiveBEV_VA + 0x480).

Requirements for Option 2 - Overlay Segments

The sole debug overlay segment is active when $ECR_{ProbeEn}=1$ and $Debug_{DM}=1$. A second overlay segment is not allowed for Debug exceptions.

The overlay segment deals with these memory requests as unmapped.

If $Config5_K=0$ and the overlay resides in a segment that is controlled by one of the $Config_{K0}$, $Config_{K23}$ and $Config_{KU}$ register fields, it is allowed for the appropriate $Config$ register field to control the cacheability attribute of the overlay segment. Otherwise, the overlay segment deals with these memory requests as uncached.

$ECR_{ProbTrap}=1$ and $ECR_{En}=1$

The debug exception vector is located at virtual address 0xFFFF.FFFF.FF20.0200. This virtual address is the same as in the legacy system.

The memory requests to that region are handled by the Debug overlay segment, which covers the Virtual address region of 0xFFFF.FFFF.FF20.0000 to 0xFFFF.FFFF.FF3F.FFFF. This overlay segment is active when $ECR_{ProbeTrap}=1$ and $ECR_{En}=1$ and $Debug_{DM}=1$. This DSEG overlay segment takes precedence over the other overlay segments.

4.13.1.5 EBase Exceptions under Segmentation Control

If $Status_{BEV}=0$, then exception vectors are located at virtual address ($Ebase[31:12] \parallel 0x000 + offset$). These virtual addresses are the same as those in the legacy system (except now the upper 2 bits of the $Ebase$ register are now also writable).

The memory requests to that region are handled by the appropriate programmable segment.

Extended Exception Vector Placement (EBase Register)

The $EBase$ register is modified to allow exception vectors to be located anywhere in the address space. See [Figure 9.45](#).

4.13.1.6 Cache Error Exceptions under Segmentation Control

The Cache Error Exception operates as defined in the base architecture, with the following additions.

Each Segment Configuration contains an EU bit. When $EU=1$, the segment becomes uncached and unmapped when $Status_{ERL}=1$. On reset, this bit is set for segments covering the range 0x00000000_00000000 to 0x00000000_7FFFFFFF, to match kuseg behavior.

On a Cache Error exception, the legacy behavior requires that bit 29 of the exception vector is set true when $Status_{BEV}=0$ and the $EBase$ register is present. This places the exception vector in the uncached kseg1 region.

Setting $Config5_{CV}=1$ allows this behavior to be overridden - the exception vector is taken directly from the $EBase$ register. This feature should be used alongside Segment Configuration EU fields to ensure that code is executed from an uncached region in the event of a Cache Error exception.

The exception vector is computed as follows:

```

if StatusBEV = 1 then
    PC ← 0xFFFF FFFF BFC0 0200 + 0x100
else
    if ArchitectureRevision ≥ 2 then
        if (Config3SC=1) and (Config5CV=1) then
            /* Use full value of EBase */
            PC ← EBase63..12 ∥ 0x100

```

```

    else
        /* EBase31..29 ignored, resulting PC always in kseg1 */
        PC ← 0xFFFF.FFFF || 1012 || EBase28..12 || 0x100
    endif
else
    PC ← 0xFFFF.FFFF.A000.0000 + 0x100
endif
endif
endif

```

4.14 Enhanced Virtual Addressing

The addition of Segmentation Control and kernel load/store instructions to the MIPS architecture provide the ability to configure virtual address ranges in the 32-bit Compatibility region that exceed prior fixed segmentation limits and to access user address space from kernel mode.

The Enhanced Virtual Addressing (EVA) feature is a configuration of Segmentation Control (refer to [Section 4.13 “Segmentation Control”](#)) and a set of kernel mode load/store instructions allowing direct access to user memory from kernel mode. In EVA, Segmentation Control is programmed to define two address ranges, a 3 GB range with mapped-user, mapped-supervisor and unmapped-kernel access modes and a 1 GB address range with mapped-kernel access mode.

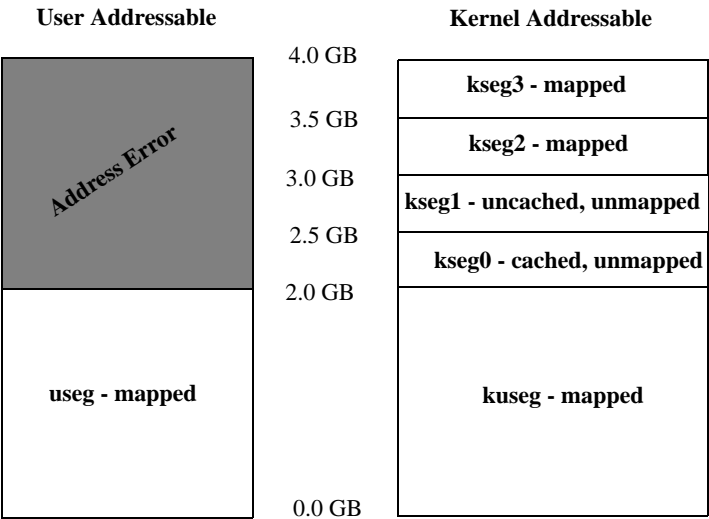

4.14.1 EVA Segmentation Control Configuration

EVA is a 2 section partitioning of the 32-bit Compatibility region virtual address space.

- 3.0GB Mapped User, Mapped Supervisor, Unmapped Kernel
- 1.0GB Mapped Kernel

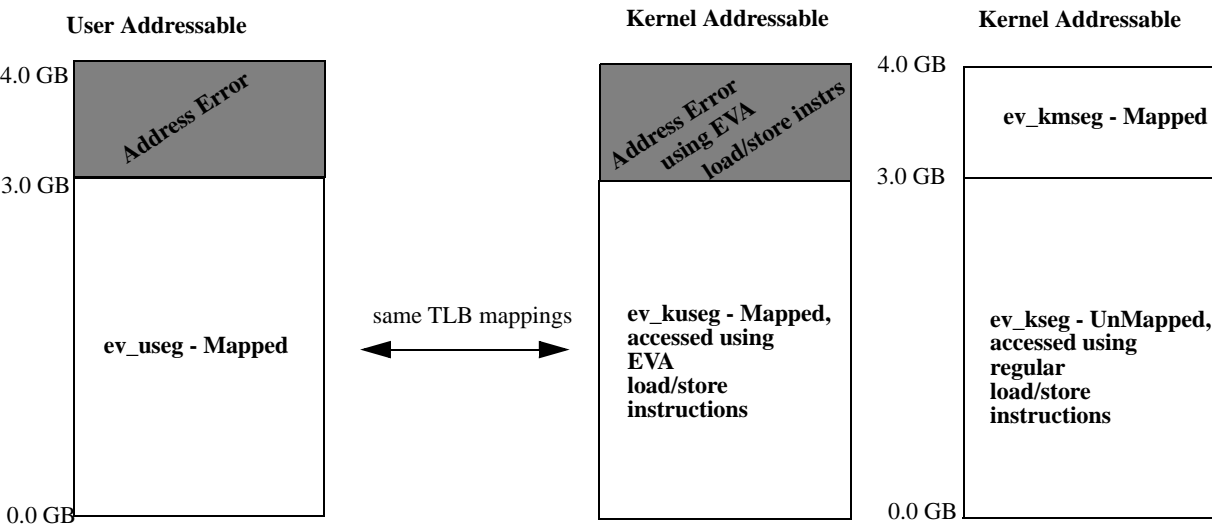

The legacy fixed segmentation of the 32-bit Compatibility region virtual address space limited user addressable memory to 2.0GB as shown in [Figure 4.4](#).

Figure 4.4 Legacy addressability

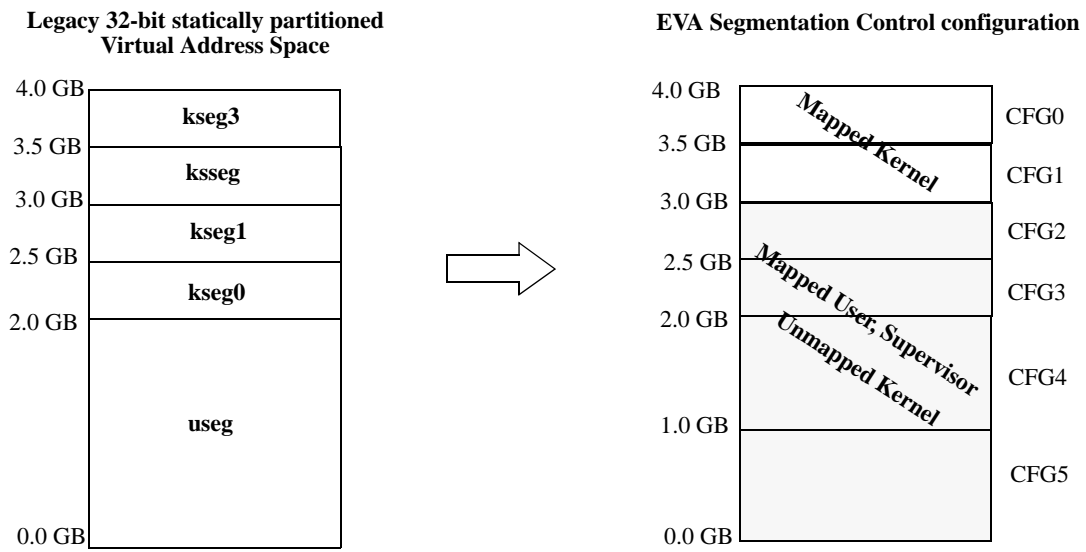

Where the EVA programmed segmentation of the 32-bit Compatibility region virtual address space extends user addressable memory to 3.0GB as shown in [Figure 4.5](#).

Figure 4.5 EVA addressability

[Figure 4.6](#) shows how the Segmentation Control CFGs remap the legacy fixed partitioning.

Figure 4.6 Legacy to EVA address configuration

To support the EVA configuration, each Segment Configuration field (CFG (defined in “Segmentation Control” on page 52)) must be initialized to define the overall memory map to support a 3GB (mapped user/supervisor, unmapped kernel) memory segment.

To configure Segmentation Control to implement EVA, the *AM*, *PA*, *C* and *EU* fields of each *CFG* are programmed as follows in the following table.

Table 4.6 Segment Configuration for 3GB EVA in 32-bit Compatibility region

CFG	Description	AM	PA	C	EU
0	1GB Mapped Kernel	MK	0x007	3	0
1		MK	0x006	3	0
2	3GB Mapped User, Supervisor, Unmapped Kernel Region	MUSUK	0x005	3	1
3		MUSUK	0x004	3	1
4		MUSUK	0x002	3	1
5		MUSUK	0x000	3	1

4.14.2 Enhanced Virtual Address (EVA) Instructions

EVA defines a number of new load/store instructions that are used to allow the kernel to access user virtual address space while executing in kernel mode

For example, the kernel can copy data from user address space to kernel physical address space by using these instructions with user virtual addresses. Kernel system-calls from user space can be conveniently changed by replacing normal load/store instructions with these instructions. Switching modes (kernel to user) is an alternative but this is

an issue if the same virtual address is being simultaneously used by the kernel. Further, there is a performance penalty in context-switching.

Limitations on use of the EVA load/store instructions are as follows:

- Only usable from Kernel execution mode.
- Only usable on a memory segment configured with a User access mode (AM).
- The address translation selected will be mapped if possible, else unmapped. More simply, a TLB based address translation is preferred.

Refer to Volume II of the MIPS Architectural Reference manual for further information on the EVA Load/Store instructions. The availability of these instructions are indicated by the *Config5_{EVA}* register field.

Table 4.7 lists kernel load/store instructions.

Table 4.7 EVA Load/Store Instructions

Instruction Mnemonic	Instruction Name
CACHEE	Perform Cache Operation EVA
LBE	Load Byte EVA
LBUE	Load Byte Unsigned EVA
LHE	Load Halfword EVA
LHUE	Load Halfword Unsigned EVA
LLE	Load-Linked EVA
LWE	Load Word EVA
LWLE	Load Word Left EVA
LWRE	Load Word Right EVA
PREFE	Prefetch EVA
SBE	Store Byte EVA
SCE	Store Conditional EVA
SHE	Store Halfword EVA
SWE	Store Word EVA
SWLE	Store Word Left EVA
SWRE	Store Word Right EVA

Table 4.8 lists the type of address translation (mapped/unmapped) performed by EVA load/store instructions according to Segmentation Control access mode (AM) and processor execution mode (defined by *StatusKSU* = Kernel, Supervisor or User). A Coprocessor 0 unusable exception is thrown if the instruction is executed in other than Kernel mode. An Address Error exception is thrown if the access mode is not allowed.

Table 4.8 Address translation behavior for EVA load/store instructions

AM- Access Mode	Kernel	Supervisor	User
UK	Address Error Excpt	COP0 Unusable Excpt	COP0 Unusable Excpt
MK	Address Error Excpt	COP0 Unusable Excpt	COP0 Unusable Excpt

Table 4.8 Address translation behavior for EVA load/store instructions

AM- Access Mode	Kernel	Supervisor	User
MSK	Address Error Excpt	COP0 Unusable Excpt	COP0 Unusable Excpt
MUSK	mapped	COP0 Unusable Excpt	COP0 Unusable Excpt
MUSUK	mapped	COP0 Unusable Excpt	COP0 Unusable Excpt
USK	Address Error Excpt	COP0 Unusable Excpt	COP0 Unusable Excpt
UUSK	unmapped	COP0 Unusable Excpt	COP0 Unusable Excpt

Table 4.9 lists the type of address translation (mapped/unmapped) performed by ordinary load/store instructions according to Segmentation Control access mode (AM) and processor execution mode (defined by *StatusKSU* = Kernel, Supervisor or User). An Address Error exception is thrown if the access mode is not allowed in the current execution mode.

Table 4.9 Address translation behavior for ordinary load/store instructions

AM - Access Mode	Kernel	Supervisor	User
UK	unmapped	Address Error Excpt	Address Error Excpt
MK	mapped	Address Error Excpt	Address Error Excpt
MSK	mapped	mapped	Address Error Excpt
MUSK	mapped	mapped	mapped
MUSUK	unmapped	mapped	mapped
USK	unmapped	unmapped	Address Error Excpt
UUSK	unmapped	unmapped	unmapped

4.15 Hardware Page Table Walker

Page Table Walking is the process by which a Page Table Entry (PTE) is located in memory. Hardware acceleration for page table walking is an optional feature in the architecture. The mechanism can be used to replace the software handler for the TLB Refill or XTLB Refill condition. This hardware mechanism is only used for this fast-path handler. This hardware mechanism is not used for the TLB Invalid handler (or slow-path handler).

The MIPS Privileged Resource Architecture (PRA) includes mechanisms intended for rapid handling of TLB exceptions in software. Following a TLB-related exception, the *Context* and *XContext* registers can provide the address of a TLB entry - calculated from the faulting virtual address and a Page Table Base address. This mechanism is effective when the OS page table is single level, the TLB entry is 16 bytes in size, and a 4k physical page size is used. Unfortunately, modern operating systems use multi-level page tables, use different page sizes, and store TLB entries in 8, 16 byte and 32-byte forms.

The existence of the Hardware Page Walking feature is denoted when $Config3_{PW}=1$.

The Hardware Page Table Walker feature additionally includes enhancements to page table entry format, as follows:

1. Huge Page support in directories (non-leaf levels of the Page Table hierarchy), and Base Page Size for the (Page Table Entry (PTE) levels (leaf levels of the Page Table hierarchy). This is the baseline definition. Inferred size PTEs are supported at non-leaf levels.
2. A reserved field has been added to PTEs. This field is for future extensions.

A Huge Page may logically be specified in two ways:

1. A Huge Page is a region composed of two power-of-4 pages which have adjacent virtual and physical addresses. Since the even page and the odd page are derived from a single directory entry, they will both inherit the same attributes and all but one of the address bits from the single directory entry. The memory region is divided evenly between the even page and the odd page. The physical address held within the directory entry is aligned to $2 \times$ size of the page (which is a power of 4). This is distinct from *EntryLo0* and *EntryLo1* pairs in the Page Table which are only guaranteed to be adjacent in virtual, but not physical address. They may also have differing page attributes. This method is known as **Adjacent Pages** since the *EntryLo0/1* physical addresses are both derived from one entry and have to be adjacent in the physical address space. This is the default method that is supported by this specification. If an implementation chooses to support Huge Pages in the directory levels, then the Adjacent Page method must be implemented.
2. Where a Huge Page is itself a power-of-4 page, it is handled in exactly the same manner as a Base Page in the Page Table. For this case, one directory entry is used for the even page and the adjacent directory entry is used for the odd page. The physical address held within the directory entry is aligned to the size of the page (which is a power of 4). This method is known as **Dual Pages** since each PFN does not have to be adjacent to each other. If an implementation chooses to support Huge Pages in the directory levels, then the Dual Page method is an additional option.

Examples of power-of-4 regions (start with 1 kB and multiply by 4 a number of times): 256 MB, 1 MB, 4 MB, 16 MB, 64 MB, 256 MB, 1GB.

Examples of $2 \times$ power-of-4 regions (start with 1 kB and multiply by 4 a number of times; then multiple by 2) 512 MB, 2 MB, 8 MB, 32 MB, 128 MB, 512 MB, 2GB.

Huge Page Support is optional and is indicated by $PWCtl_{Hugepg}=1$. If an Implementation supports Huge Pages in the directory levels, it must support the Adjacent Page method. The Dual Page method is optional if Huge Pages are supported. The implementation of Dual Page method is indicated by $PWCtl_{DPH}=1$

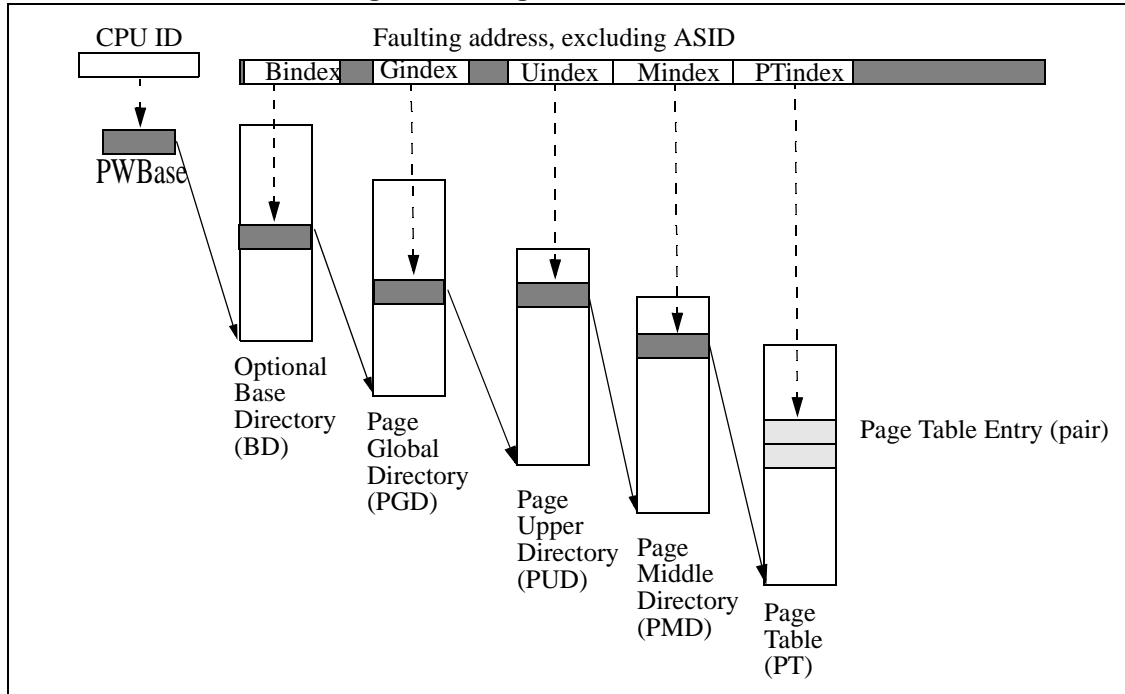

4.15.1 Multi-Level Page Table support

The hardware page table walking system specifies a mechanism for refilling the TLB, independent of the *Context* and *XContext* registers. Four additional coprocessor 0 registers are added. The *PWBase* register specifies the per-VPE page table base. The *PWField* and *PWSize* registers specify address generation for up to five levels of page table. The *PWCtl* register controls the behavior of the Page Table Walker. These registers also configure the separation between Page Table Entries (PTEs) in memory and post-load shifting of PTEs.

A multi-level page table system forms a tree structure - the lowest (leaf) elements of which are Page Tables. A Page Table is an array of Page Table Entries. Levels above the Page Tables are known as Directories. A Directory consists of an array of pointers. Each pointer in a Directory is either to another Directory or to a Page Table.

The next figure shows an example of a multi-level page table structure.

Figure 4.7 Page Table Walk Process

Each executing process is typically associated with a separate page table base pointer (*PWBBase*). In a single-threaded, uniprocessor system, only one process is active at once. Where multiple CPUs or VPEs are in use, multiple processes execute simultaneously - thus one page table base pointer is required per CPU or VPE. The term 'page table base' refers to the start of a Base Directory (optional) or Page Global Directory.

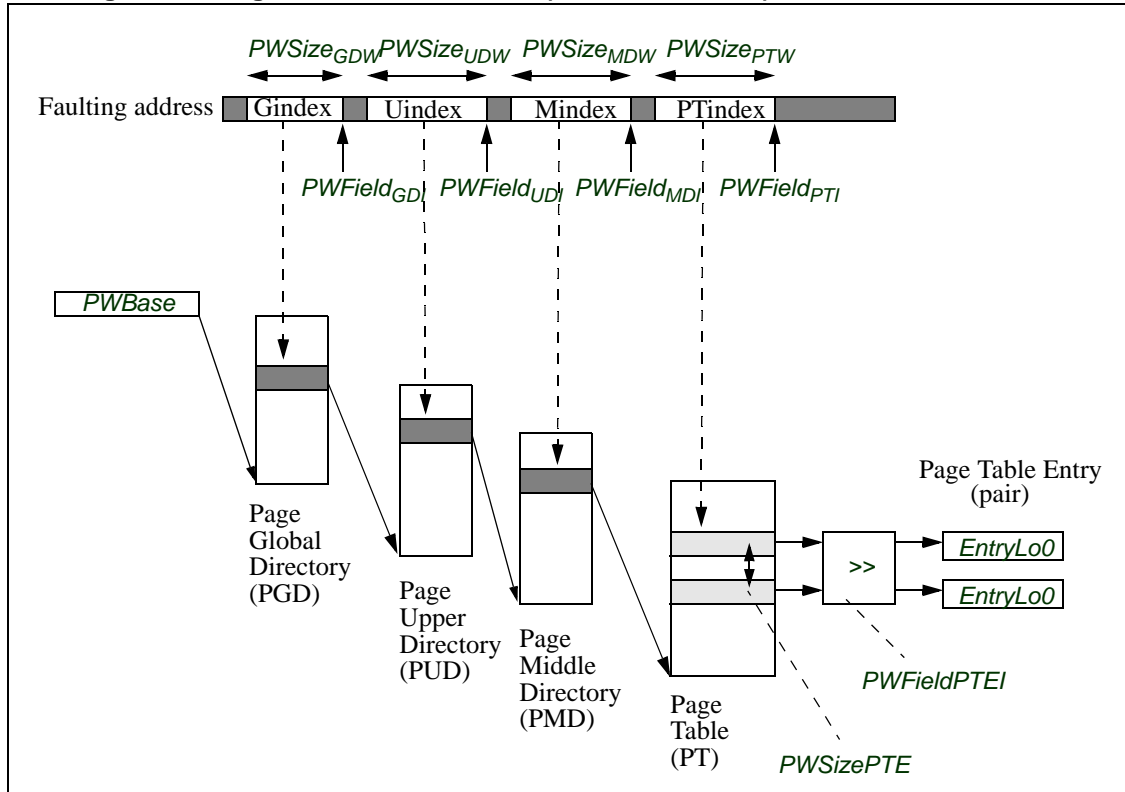

A typical page table structure consists of:

- A per CPU/VPE *PWBBase* register, containing the base of the (optional) Base Directory or Page Global Directory.
- Page Global Directories, indexed by upper bits from the faulting address, containing pointers to Page Upper Directories.
- Page Upper Directories, indexed by bits from the faulting address, containing pointers to Page Middle Directories.
- Page Middle Directories, indexed by bits from the faulting address, containing pointers to Page Tables.
- Page Tables, indexed by bits from the faulting address, containing Page Table Entry (PTE) pairs.

In some 64-bit systems, the Page Upper Directories are not used. In some 32-bit systems, the Page Upper Directories and Page Middle Directories are not used. Some systems may wish to exclude certain bits of the faulting address when performing a page table walk - this is most likely in 64-bit systems. Some systems use bits in the Page Table Entries to store OS-specific flags, which are removed using a shift before writing into EntryLo0/1. Other systems store these flags alongside the PTEs. Some hardware implementations may seek to include more than one page table walker, allowing out-of-order execution to continue despite multiple TLB misses.

The hardware page table walking scheme takes account of all these possibilities.

Figure 4.8 shows the registers and fields used by the page table walking scheme for a four level page table structure.

Figure 4.8 Page Table Walk Process (without Base Dir) & COP0 Control fields

Hardware page table walking is performed when enabled and a TLB or XTLB refill condition is detected.

Hardware page table walking is enabled when

// it's globally enabled and

$PWctl_{PWE_n}=1$ and

// There's a page table structure to walk

$((PWctl_{PWDirExt}=1 \ \& \ PWSIZE_{BDW}>0) \mid PWSIZE_{GDW}>0 \mid PWSIZE_{UDW}>0 \mid PWSIZE_{MDW}>0)$ and

// and there's a segment to map

$((PWSIZE_{PS}=0) \mid (PWSIZE_{PS}=1 \ \& \ (PWctl_{XK}=1 \mid PWctl_{XS}=1 \mid PWctl_{XU}=1)))$.

Hardware page table walking is not allowed if the CCA of the access is uncached, or if the address matches a MAAR that is non-speculative. CP0 MAAR is defined in Release 5 of the architecture.

Memory reads during hardware page table walking are performed as if they were kernel-mode load instructions. Addresses contained in the *PWBase* register and in memory-resident directories are virtual addresses.

Physical addresses and cache attributes are obtained from the Segment Configuration system when *Config3_{SC}*=1, or from the default MIPS segment system when *Config3_{SC}*=0.

The hardware page walk write should treat the multiple-hit case the same as a TLBWR. Assuming that the write by design cannot detect all duplicates, then a preferred implementation is to invalidate the single duplicate and then write the TLB. A Machine Check exception may subsequently be taken on a TLBP or lookup of TLB.

If a synchronous exception condition is detected during the hardware page table walk, the HW walking process is aborted and a TLB Refill or XTLB Refill exception will be taken, as appropriate. This includes synchronous exceptions such as Address Error, Precise Debug Data Break and other TLB exceptions resulting from accesses to mapped regions.

If an asynchronous exception is detected during the hardware page table walk, the HW walking process is aborted and the asynchronous exception is taken. This includes asynchronous exceptions such as NMI, Cache Error, and Interrupts. It also includes the asynchronous Machine Check exception which results from multiple matching entries being present in the TLB following a TLB write.

Implementations are not required to support hardware page table walk reads from mapped regions of the Virtual Address space. If an implementation does not support reads from mapped regions, an attempted access during a page table walk will cause the process to be aborted, and a TLB Refill or XTLB Refill exception will be taken, as appropriate.

On 64-bit machines, the hardware page table walk can be used to accelerate TLB refills for either 32 bit or 64 bit address regions, but not both. The *PWSize_{PS}* field controls whether pointers within Directories are treated as 32 or 64 bit addresses.

The selection between TLB and XTLB Refill exception is determined from the faulting address and the UX, SX and KX bits in the *Status* register. See the MIPS64 Privileged Resource Architecture document for details.

Hardware page table walking is performed as follows:

1. A temporary pointer is loaded with the contents of the *PWBase* register
2. The native pointer size is determined from the *PWSize_{PS}* field - either 4 bytes (32 bits) or 8 bytes (64 bits)
3. If the (optional) Base Directory is disabled by *PWCtl_{PWDirExt}*=0, skip to the next step.
 - If Huge Pages are supported, check PTEVld bit to determine if entry is PTE. If PTEVld bit is set, write Huge Page into TLB (details left out for brevity, read pseudo-code at end of this section). Page Walking is complete after Huge Page is written to TLB.
 - Extract *PWSize_{BDW}* bits from the faulting address, with least-significant bit *PWField_{BDI}*. This is the optional Base Directory index (Bindex). Logical OR onto the temporary pointer, after multiplying (shifting) by the native pointer size. The result is a pointer to a location within the Base Directory.
 - Perform a memory read from the address in the temporary pointer, of the native pointer size. The returned value is placed into the temporary pointer. If an exception is detected, abort.
4. If the Global Directory is disabled by *PWSize_{GDW}*=0, skip to the next step.
 - If Huge Pages are supported, check PTEVld bit to determine if entry is PTE. If PTEVld bit is set, write Huge Page into TLB (details left out for brevity, read pseudo-code at end of this section). Page Walking is complete after Huge Page is written to TLB.

Virtual Memory

- Extract $PWSize_{GDW}$ bits from the faulting address, with least-significant bit $PWField_{GDI}$. This is the Global Directory index (Gindex). Logical OR onto the temporary pointer, after multiplying (shifting) by the native pointer size. The result is a pointer to a location within the Global Directory.
 - Perform a memory read from the address in the temporary pointer, of the native pointer size. The returned value is placed into the temporary pointer. If an exception is detected, abort.
5. If the Upper Directory is disabled by $PWSize_{UDW}=0$, skip to the next step.
- If Huge Pages are supported, check PTEVld bit to determine if entry is PTE. If PTEVld bit is set, write Huge Page into TLB (details left out for brevity, read pseudo-code at end of this section). Page Walking is complete after Huge Page is written to TLB.
 - Extract $PWSize_{UDW}$ bits from the faulting address, with least-significant bit $PWField_{UDI}$. This is the Upper Directory index (Uindex). Logical OR onto the temporary pointer, after multiplying (shifting) by the native pointer size. The result is a pointer to a location within the Upper Directory.
 - Perform a memory read from the address in the temporary pointer, of the native pointer size. The returned value is placed into the temporary pointer. If an exception is detected, abort.
6. If the Middle Directory is disabled by $PWSize_{MDW}=0$, skip to the next step.
- If Huge Pages are supported, check PTEVld bit to determine if entry is PTE. If PTEVld bit is set, write Huge Page into TLB (details left out for brevity, read pseudo-code at end of this section). Page Walking is complete after Huge Page is written to TLB.
 - Extract $PWSize_{MDW}$ bits from the faulting address, with least-significant bit $PWField_{MDI}$. This is the Middle Directory index (Mindex). Logical OR onto the temporary pointer, after multiplying (shifting) by the native pointer size. The result is a pointer to a location within the Middle Directory.
 - Perform a memory read from the address in the temporary pointer, of the native pointer size. The returned value is placed into the temporary pointer. If an exception is detected, abort.
 - The temporary pointer now contains the address of the Page Table to be used.
7. Extract $PWSize_{PTW}$ bits from the faulting address, with least-significant bit $PWField_{PTI}$. This is the Page Table index (PTindex). Multiply (shift) by the native pointer size, then multiply (shift) by the size of the Page Table Entry, specified in $PWSize_{PTEW}$.
- The temporary pointer now contains the address of the first half of the Page Table Entry.
 - Perform a memory read from the address in the temporary pointer, of the native pointer size. The returned value is logically shifted right by $PWField_{PTEI}$ bits. This is the first half of the Page Table Entry. If an exception is detected, abort.
8. In the temporary pointer, set the bit located at bit location $PWField_{PTEF}$ 1.
- The temporary pointer now contains the address of the second half of the Page Table Entry.
 - Perform a memory read from the address in the temporary pointer, of the native pointer size. The returned value is shifted right by $PWField_{PTEI}$ bits. This is the second half of the Page Table Entry. If an exception is detected, abort.

9. Write the two halves of the Page Table Entry into the TLB, using the same semantics as the TLBWR (TLB write random) instruction.
10. Continue with program execution.

Coprocessor 0 registers which are used by software on TLB or XTLB refill exceptions are unused by the hardware page table walking process. The registers and fields used by software are *BadVAddr*, *EntryHi*, *PageMask*, *EntryLo0*, *EntryLo1*, *XContext_{BadVPN2}* and *Context_{BadVPN2}*.

4.15.2 PTE and Directory Entry Format

All entries are read from in-memory data structures. There are three types of entries in the baseline definition: Directory Pointer, Huge Page non-leaf PTE of inferred size, and leaf PTE of base size. For options other than baseline, the entry type is a function of the table level and the PTEvld field of an entry. For all but the last level table (leaf level), the PTEvld bit is 0 for directory pointers to the next table and 1 for PTEs. In the leaf table, the entry is always a PTE and the PTEvld bit is not used by Hardware Walker. The *PWCtrl_{HugePg}* register field indicates whether Huge Page non-leaf PTEs are implemented.

All PTEs are shifted right by *PWField_{PTEI}*-2 (shifting in zeros at the most significant bit) and then rotated right by 2 bits before forming the page-walker equivalents of *EntryLo0* and *EntryLo1* values. These operations are used to remove the Software-only bits and placing the RI and XI protection bits in the proper bit location before writing the TLB. If the RI and XI bits are implemented and enabled, the HW Page Walker feature requires the RI bit to be placed right of the G bit in the PTE memory format. Similarly, it is required that the XI bit to be placed right of the RI bit in the PTE memory format.

Note that whether the mode of operation is 32b-compatible or native 64b, the RI/XI bits will always end up in bits 63:62 of the rotated PTE because the rotate is always 64b in the page walker. This is in contrast to mtc0/mfc0 instructions used by the software refill handler which explicitly shift bits 31:30 to 63:62 if the move is to/from EntryLo0/1. Refer to instruction descriptions for MTC0 and MFC0 in Volume II for more information.

Note that the bit position of PTEvld is not fixed at 0. It can be programmed by the *PWCtrl_{PSn}* field. If non-leaf PTE entries are available, there will already be a bit used by the software TLB handler to distinguish non-leaf PTE entries from directory pointers. Normally, the PTEvld bit is configured to point to that software bit within the PTE.

A possible programming error to avoid is placing the PTEvld bit within the Directory Pointer field, as any of those address bits may be set and thus not appropriate to be used to distinguish between a Directory Pointer or a non-leaf PTE.

The following figures show an example of 8-byte pointers or PTE entries. The 8-byte width is configured by the combination of *PWSize_{PS}*=1 and *PWSize_{PTEW}*=0. In this example, 8 bits are used for Software-only flags. The following figures assume a PTE format based on *PWCtrl_{PSn}*=0, *PWField_{PTEI}*=10 and a Base Page Size of 4k for simplicity. In this example, the

Figure 4.9 8-byte Leaf PTE

63..40	39		16	15..13	12	11	10	9	8		7..0	Comment

Non-leaf PTE	RI	XI	FILL	PFNX	PFN	Rsvd (must be 0)	C	D	V	G	Page Size=HgPgSz

Leaf PTEs always occur in pairs (*EntryLo0* and *EntryLo1*). However, non-leaf PTEs (ones which occur in the upper directories) can occur either in pairs (if Dual Page method is enabled) or occur with just one entry (Adjacent Page method).

For the Adjacent Page method, the single non-leaf PTE represent both *EntryLo0* and *EntryLo1* values. When the walker populates the EntryLo registers for a PTE in a directory, the least significant bit above the page size is 0 for *EntryLo0* and 1 for *EntryLo1*. That is, *EntryLo0* and *EntryLo1* represent adjacent physical pages.

For the Dual Page method, the two PTEs are read from the directory level by the Hardware Page Walker.

For Huge Page handling, the size of the Huge Page is inferred from the directory level in which the Huge Page resides. For the Adjacent Page Method, the size of each individual PTE in *EntryLo0* and *EntryLo1* as synthesized from the single Huge Page is always half the inferred size.

If the inferred page size is 2 x power-of-4, then the Adjacent Page Method is used.

If the inferred page size is a power-of-4, then the Dual Page Method is used (if the Dual Page Method is implemented). If the Dual Page method is implemented ($PWCtl_{DPH}=1$), it is implementation-specific whether the PTEVld bit is checked for the second PTE when it is read from memory for writing the second TLB page. The recommended behavior is to check this second PTEVld bit and if it is not set, a Machine Check exception is triggered. The *PageGrain_{MCCause}* register field is used to differentiate between different types of Machine Check exceptions.

If the inferred Huge Page size is power-of-4, and the Dual Page Methods is not implemented, it is implementation-specific whether a Machine Check is reported.

An example of Huge Page handling follows. It assumes a leaf PTE size of 4 kB.

- PMD Huge Page = $2^9 (PWSize_{PTW}) * 2^{12} (PWField_{PTI}) = 2^{21} = 2 \text{ MB}$. Each EntryLo0/1 page is 1 MB, which is a power-of-4 and use the Adjacent Page method.
- PUD Huge Page = $2^{10} (PWSize_{MDW}) * 2^9 (PWSize_{PTW}) * 2^{12} (PWField_{PTI}) = 2^{31} = 2 \text{ GB}$. Each EntryLo0/1 page is 1GB, which is a power-of-4 and would use the Adjacent Page method. Note that the index into PMD has been extended to 10 bits from 9 bits. Each PMD table thus has 1K entries instead of the typical 512 entries.

4.15.3 Hardware page table walking process

The hardware page table walking process is described in pseudocode as follows:

```
/* Perform hardware page table walk
 *
 * Memory accesses are performed using the KERNEL privilege level.
 * Synchronous exceptions detected on memory accesses cause a silent exit
 * from page table walking, resulting in a TLB or XTLB Refill exception.
 *
 * Implementations are not required to support page table walk memory
 * accesses from mapped memory regions. When an unsupported access is
 * attempted, a silent exit is taken, resulting in a TLB or XTLB Refill exception.
 *
 * Note that if an exception is caused by AddressTranslation or LoadMemory
 * functions, the exception is not taken, a silent exit is taken,
 * resulting in a TLB or XTLB Refill exception.
 *
 * For readability, this pseudo-code does not deal with PTEs of different widths.
 * In reality, implementations will have to deal with the different PTE
 * and directory pointer widths.
 */
subroutine PageTableWalkRefill(vAddr) :
```

endsub

```

If a page is marked invalid, the hardware refill handler will still fill the page into the TLB. Software can point to invalid PTEs to represent regions that are not mapped. When the Software attempts to use the invalid TLB entry, a TLB invalid exception will be generated.

Common Device Memory Map

MIPS processors may include memory-mapped IO devices that are packaged as part of the CPU. An example is the Fast Debug Channel, which is a UART-like communication device that uses the EJTAG probe pins to move data to the external world.

The Common Device Memory Map (CDMM) is a region of physical address space that is reserved for mapping IO device configuration registers within a MIPS processor. The CDMM helps aggregate various device mappings into one area, preventing fragmentation of the memory address space. It also enables the use of access control and memory address translation mechanisms for these device registers. The CDMM occupies a maximum of 32 kB in the physical address map.

The CDMM is an optional feature of the architecture. Software detects if CDMM is implemented by reading the `Config3CDMM` register field (bit 3).

Two blocks are defined for the CDMM -

- `CDMMBase` - A new Coprocessor 0 register that sets the base physical address of the CDMM
- CDMM Access Control and Device Register Block - The 32 kB CDMM region is divided into smaller 64-byte aligned blocks called 'Device Register Blocks' (DRBs). Each block has access control and status information in access control and status registers (ACSRs), followed by IO device registers.

For implementations that have multiple VPEs, the IO devices and their ACSRs are instantiated once per VPE, but the `CDMMBase` register is shared among the VPEs.

Implementations are not required to maintain cache coherence for the CDMM region. For that reason, the memory mapped registers located within this region must be accessed only using uncached memory transactions. Accessing these registers using a cacheable CCA may result in **UNPREDICTABLE** behavior.

Each of these blocks are now described in detail.

5.1 CDMMBase Register

The physical base address for the CDMM facility is defined by a coprocessor 0 register called `CDMMBase`, (CP0 register 15, select 2). This address must be aligned to a 32 kB boundary.

On a 64-bit core with a TLB-based MMU, this region would most likely be mapped to a physical address which can be accessed through one of the kernel unmapped, uncached virtual address segments (kseg1 or xkphys). User-mode access could be allowed through a TLB mapping using an uncached coherency.

On cores that use a FMT MMU, the region would most likely be mapped to the lower 512 MB and made accessible via kernel mode. Alternatively, if user-mode access is allowed, this region could be mapped to correspond to the kuseg physical address segment.

On cores that use a BAT MMU, if only kernel mode access is allowed, the region would be mapped to a physical address region reachable through kseg1 or kseg2/3 (using uncached coherency). If user mode access is allowed, the useg BAT entry must use an uncached coherency.

Please refer to [Section 9.43 on page 253](#) for the description of the *CDMMBase* register.

5.2 CDMM - Access Control and Device Register Blocks

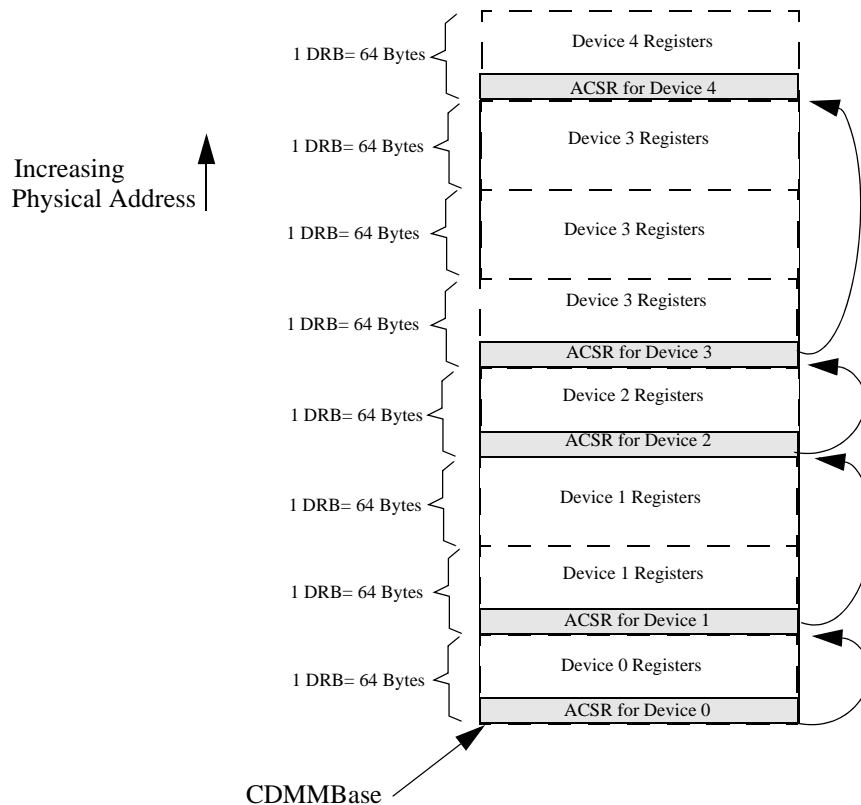

The CDMM is divided into 64-byte aligned segments named ‘Device Register Blocks’ (DRBs). Each device occupies at least one DRB. If a device needs additional address space, it can occupy multiple contiguous 64-byte blocks, e.g., multiple DRBs which are adjacent in the physical address map. For each device, device type identification and access control information is located in the DRB allocated for the device with the lowest physical address.

Access control information is specified via ‘Access Control and Status Registers’ (ACSRs) that are found at the start of the DRB allocated for the device with the lowest physical address. The ACSR for a device holds the size of the IO device, and hence also act as a pointer to the start of the next device and its’ ACSR. ACSRs are only accessible in kernel mode. The ACSR is followed by the data/control registers for the IO device. [Figure 5.1](#) shows the organization of the CDMM.

Reading any of the IO device registers in either usermode or supervisor mode when such accesses are not allowed, results in all zeros being returned. Writing any of the IO device registers in either usermode or supervisor mode when such accesses are not allowed, results in the write being ignored and the register not being modified. Reading any of the ACSR registers while not in kernel mode results in all zeros being returned. Writing any of the ACSR registers while not in kernel mode results in the write being ignored and the ACSR not being modified.

Since the ACSR act as a pointer that can only increment, the devices must be allocated in the memory space in a specific manner. The first device must be located at the address pointed by the *CDMMBase* register and any subsequent device is allocated in the next available adjacent DRB.

If the *CI* bit is set in the *CDMMBASE* register, the first DRB of the CDMM (at offset 0x0 from the *CDMMBase*) is reserved for implementation specific use.

Figure 5.1 Example Organization of the CDMM

5.2.1 Access Control and Status Registers

The first DRB of a device has 8 bytes of access control address space allocated to it. These 8 bytes can be considered to be two 32-bit registers (on a 32-bit or 64-bit core), or a single 64-bit register (on a 64-bit core). In revision 1.00 of the CDMM, only the lower 32-bits hold access control and status information. The control/status register can be accessed in kernel mode only. Reading this register while not in kernel mode results in all zeros being returned. Writing this register while not in kernel mode results in the write being ignored and the register not being modified.

[Figure 5.2](#) has the format of an Access Control and Status register (shown as a 64-bit register), and [Table 5.1](#) describes the register fields.

Table 5.1 Access Control and Status Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
DevType	31:24	This field specifies the type of device. A non-zero value indicates the type of device. A zero value indicates the absence of a device.	R	Preset	Required

Table 5.1 Access Control and Status Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
DevSize	21:16	This field specifies the number of extra 64-byte blocks allocated to this device. A value of 0 indicates that only one 64-byte block is allocated. This also determines the location of the next device block. A device is limited to 4 kB of memory.	R	Preset	Required
DevRev	15:12	This field specifies the revision of device. This field is combined with the DevType field to denote the specific device revision.	R	Preset	Required
Uw	3	This bit indicates if user-mode write access to this device is enabled. A value of 1 indicates that access is enabled. A value of 0 indicates that access is disabled. An attempt to write to the device while in user mode with access disabled is ignored.	R/W	0	Required
Ur	2	This bit indicates if user-mode read access to this device is enabled. A value of 1 indicates that access is enabled. A value of 0 indicates that access is disabled. An attempt to read from the device while in user mode with access disabled is ignored.	R/W	0	Required
Sw	1	This bit indicates if supervisor-mode write access to this device is enabled. A value of 1 indicates that access is enabled. A value of 0 indicates that access is disabled. An attempt to write to the device while in supervisor mode with access disabled is ignored.	R/W	0	Required
Sr	0	This bit indicates if supervisor-mode read access to this device is enabled. A value of 1 indicates that access is enabled. A value of 0 indicates that access is disabled. An attempt to read from the device while in supervisor mode with access disabled is ignored.	R/W	0	Required
0	63:32, 11:4	Reserved for future use. Ignored on write; returns zero on read.	R	0	Required

Interrupts and Exceptions

Release 2 of the Architecture added the following features related to the processing of Exceptions and Interrupts:

- The addition of the Coprocessor 0 *EBase* register, which allows the exception vector base address to be modified for exceptions that occur when *Status_{BEV}* equals 0. The *EBase* register is required.
- The extension of the Release 1 interrupt control mechanism to include two optional interrupt modes:
 - Vectored Interrupt (VI) mode, in which the various sources of interrupts are prioritized by the processor and each interrupt is vectored directly to a dedicated handler. When combined with GPR shadow registers, introduced in the next chapter, this mode significantly reduces the number of cycles required to process an interrupt.
 - External Interrupt Controller (EIC) mode, in which the definition of the coprocessor 0 register fields associated with interrupts changes to support an external interrupt controller. This can support many more prioritized interrupts, while still providing the ability to vector an interrupt directly to a dedicated handler and take advantage of the GPR shadow registers.
- The ability to stop the *Count* register for highly power-sensitive applications in which the *Count* register is not used, or for reduced power mode. This change is required.
- The addition of the DI and EI instructions which provide the ability to atomically disable or enable interrupts. Both instructions are required.
- The addition of the *TI* and *PCI* bits in the *Cause* register to denote pending timer and performance counter interrupts. This change is required.
- The addition of an execution hazard sequence which can be used to clear hazards introduced when software writes to a coprocessor 0 register which affects the interrupt system state.

6.1 Interrupts

Release 1 of the Architecture included support for two software interrupts, six hardware interrupts, and two special-purpose interrupts: timer and performance counter. The timer and performance counter interrupts were combined with hardware interrupt 5 in an implementation-dependent manner. Interrupts were handled either through the general exception vector (offset 0x180) or the special interrupt vector (0x200), based on the value of *Cause_{IP}*. Software was required to prioritize interrupts as a function of the *Cause_{IP}* bits in the interrupt handler prologue.

Release 2 of the Architecture adds an upward-compatible extension to the Release 1 interrupt architecture that supports vectored interrupts. In addition, Release 2 adds a new interrupt mode that supports the use of an external interrupt controller by changing the interrupt architecture.

Although a Non-Maskable Interrupt (NMI) includes “interrupt” in its name, it is more correctly described as an NMI exception because it does not affect, nor is it controlled by the processor interrupt system.

Interrupts and Exceptions

An interrupt is only taken when all of the following are true:

- A specific request for interrupt service is made, as a function of the interrupt mode, described below.
- The *IE* bit in the *Status* register is a one.
- The *DM* bit in the *Debug* register is a zero (for processors implementing EJTAG)
- The *EXL* and *ERL* bits in the *Status* register are both zero.

Logically, the request for interrupt service is ANDed with the *IE* bit of the *Status* register. The final interrupt request is then asserted only if both the *EXL* and *ERL* bits in the *Status* register are zero, and the *DM* bit in the *Debug* register is zero, corresponding to a non-exception, non-error, non-debug processing mode, respectively.

6.1.1 Interrupt Modes

An implementation of Release 1 of the Architecture only implements interrupt compatibility mode.

An implementation of Release 2 of the Architecture may implement up to three interrupt modes:

- Interrupt compatibility mode, which acts identically to that in an implementation of Release 1 of the Architecture. This mode is required.
- Vectored Interrupt (VI) mode, which adds the ability to prioritize and vector interrupts to a handler dedicated to that interrupt, and to assign a GPR shadow set for use during interrupt processing. This mode is optional and its presence is denoted by the *VInt* bit in the *Config3* register.
- External Interrupt Controller (EIC) mode, which redefines the way in which interrupts are handled to provide full support for an external interrupt controller handling prioritization and vectoring of interrupts. This mode is optional and its presence is denoted by the *VEIC* bit in the *Config3* register.

A compatible implementation of Release 2 of the Architecture must implement interrupt compatibility mode, and may optionally implement one or both vectored interrupt modes. Inclusion of the optional modes may be done selectively in the implementation of the processor, or they may always be implemented and be dynamically enabled based on coprocessor 0 control bits. The reset state of the processor is to interrupt compatibility mode such that an implementation of Release 2 of the Architecture is fully compatible with implementations of Release 1 of the Architecture.

Table 6.1 shows the current interrupt mode of the processor as a function of the coprocessor 0 register fields that can affect the mode.

Table 6.1 Interrupt Modes

<i>Status</i> _{BEV}	<i>Cause</i> _{IV}	<i>IntCtl</i> _{VS}	<i>Config3</i> _{VINT}	<i>Config3</i> _{VEIC}	Interrupt Mode
1	x	x	x	x	Compatibility
x	0	x	x	x	Compatibility
x	x	=0	x	x	Compatibility
0	1	≠0	1	0	Vectored Interrupt
0	1	≠0	x	1	External Interrupt Controller

Table 6.1 Interrupt Modes (Continued)

Status _{BEV}	Cause _{IV}	IntCtl _{VS}	Config3 _{VINT}	Config3 _{VEIC}	Interrupt Mode
0	1	≠0	0	0	Not Allowed - IntCtl _{VS} is zero if neither Vectored Interrupt nor External Interrupt Controller mode are implemented.
“x” denotes don’t care					

6.1.1.1 Interrupt Compatibility Mode

This is the only interrupt mode for a Release 1 processor and the default interrupt mode for a Release 2 processor. This mode is entered when a Reset exception occurs. In this mode, interrupts are non-vectored and dispatched through exception vector offset 0x180 (if Cause_{IV} = 0) or vector offset 0x200 (if Cause_{IV} = 1). This mode is in effect if any of the following conditions are true:

- Cause_{IV} = 0
- Status_{BEV} = 1
- IntCtl_{VS} = 0, which would be the case if vectored interrupts are not implemented, or have been disabled.

The current interrupt requests are visible via the IP field in the Cause register on any read of the register (not just after an interrupt exception has occurred). Note that an interrupt request may be deasserted between the time the processor starts the interrupt exception and the time that the software interrupt handler runs. The software interrupt handler must be prepared to handle this condition by simply returning from the interrupt via ERET. A request for interrupt service is generated as shown in Table 6.2.

Table 6.2 Request for Interrupt Service in Interrupt Compatibility Mode

Interrupt Type	Interrupt Source	Interrupt Request Calculated From
Hardware Interrupt, Timer Interrupt, or Performance Counter Interrupt	HW5	Cause _{IP7} and Status _{IM7}
Hardware Interrupt	HW4	Cause _{IP6} and Status _{IM6}
	HW3	Cause _{IP5} and Status _{IM5}
	HW2	Cause _{IP4} and Status _{IM4}
	HW1	Cause _{IP3} and Status _{IM3}
	HW0	Cause _{IP2} and Status _{IM2}
Software Interrupt	SW1	Cause _{IP1} and Status _{IM1}
	SW0	Cause _{IP0} and Status _{IM0}

A typical software handler for interrupt compatibility mode might look as follows:

```
/*
 * Assumptions:
 * - CauseIV = 1 (if it were zero, the interrupt exception would have to
```

Interrupts and Exceptions

```
*           be isolated from the general exception vector before getting
*           here)
* - GPRs k0 and k1 are available (no shadow register switches invoked in
*                               compatibility mode)
* - The software priority is IP7..IP0 (HW5..HW0, SW1..SW0)
*
* Location: Offset 0x200 from exception base
*/

IVexception:

    nop

/*
* Each interrupt processing routine processes a specific interrupt, analogous
* to those reached in VI or EIC interrupt mode. Since each processing routine
* is dedicated to a particular interrupt line, it has the context to know
* which line was asserted. Each processing routine may need to look further
* to determine the actual source of the interrupt if multiple interrupt requests
* are ORed together on a single IP line. Once that task is performed, the
* interrupt may be processed in one of two ways:
*
* - Completely at interrupt level (e.g., a simply UART interrupt). The
*   SimpleInterrupt routine below is an example of this type.
* - By saving sufficient state and re-enabling other interrupts. In this
*   case the software model determines which interrupts are disabled during
*   the processing of this interrupt. Typically, this is either the single
*   StatusIM bit that corresponds to the interrupt being processed, or some
*   collection of other StatusIM bits so that "lower" priority interrupts are
*   also disabled. The NestedInterrupt routine below is an example of this type.
*/

SimpleInterrupt:
/*
* Process the device interrupt here and clear the interrupt request
* at the device. In order to do this, some registers may need to be
* saved and restored. The coprocessor 0 state is such that an ERET
* will simply return to the interrupted code.
*/
    eret                    /* Return to interrupted code */

NestedException:
/*
* Nested exceptions typically require saving the EPC and Status registers,
* any GPRs that may be modified by the nested exception routine, disabling
* the appropriate IM bits in Status to prevent an interrupt loop, putting
* the processor in kernel mode, and re-enabling interrupts. The sample code
* below cannot cover all nuances of this processing and is intended only
```

```

* to demonstrate the concepts.
*/

dmtc0  k1, C0_EPC     /* and EPC */
/* Restore GPRs and software state */
eret   /* Dismiss the interrupt */

```

6.1.1.2 Vectored Interrupt Mode

Vectored Interrupt mode builds on the interrupt compatibility mode by adding a priority encoder to prioritize pending interrupts and to generate a vector with which each interrupt can be directed to a dedicated handler routine. This mode also allows each interrupt to be mapped to a GPR shadow set for use by the interrupt handler. Vectored Interrupt mode is in effect if all of the following conditions are true:

- $Config3_{VInt} = 1$
- $Config3_{VEIC} = 0$
- $IntCt_{IVS} \neq 0$
- $Cause_{IV} = 1$
- $Status_{BEV} = 0$

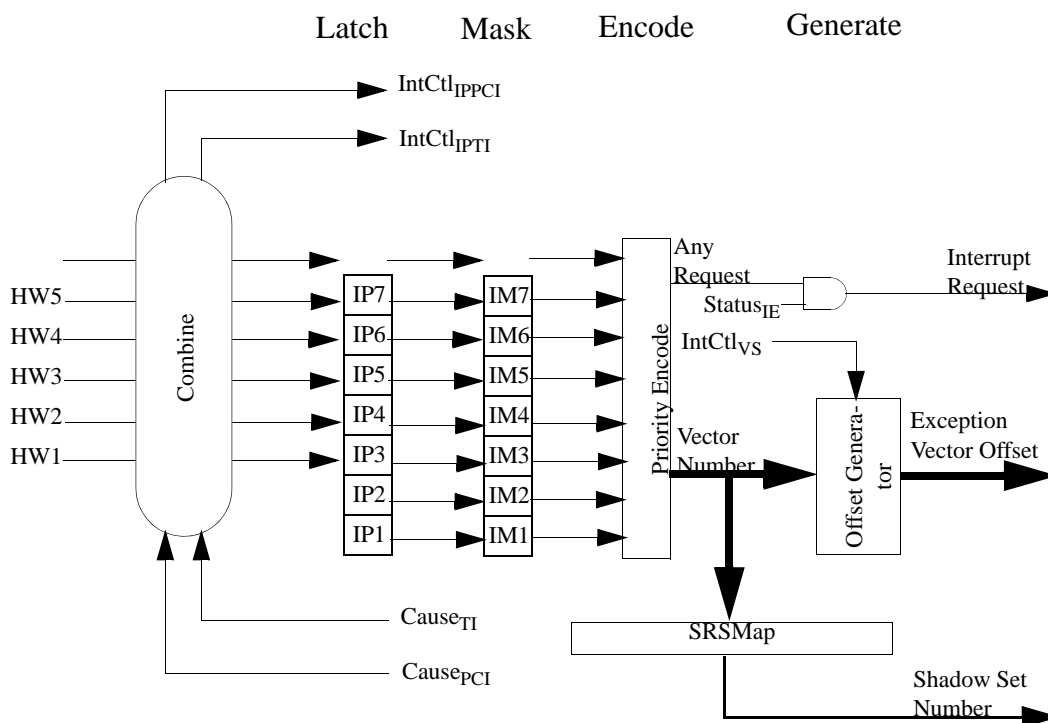

Interrupts and Exceptions

In VI interrupt mode, the six hardware interrupts are interpreted as individual hardware interrupt requests. The timer and performance counter interrupts are combined in an implementation-dependent way with the hardware interrupts (with the interrupt with which they are combined indicated by $IntCtl_{IPTI}$ and $IntCtl_{IPPCl}$, respectively) to provide the appropriate relative priority of these interrupts with that of the hardware interrupts. The processor interrupt logic ANDs each of the $Cause_{IP}$ bits with the corresponding $Status_{IM}$ bits. If any of these values is 1, and if interrupts are enabled ($Status_{IE} = 1$, $Status_{EXL} = 0$, and $Status_{ERL} = 0$), an interrupt is signaled and a priority encoder scans the values in the order shown in [Table 6.3](#).

Table 6.3 Relative Interrupt Priority for Vectored Interrupt Mode

Relative Priority	Interrupt Type	Interrupt Source	Interrupt Request Calculated From	Vector Number Generated by Priority Encoder
Highest Priority	Hardware	HW5	$Cause_{IP7}$ and $Status_{IM7}$	7
		HW4	$Cause_{IP6}$ and $Status_{IM6}$	6
		HW3	$Cause_{IP5}$ and $Status_{IM5}$	5
		HW2	$Cause_{IP4}$ and $Status_{IM4}$	4
		HW1	$Cause_{IP3}$ and $Status_{IM3}$	3
		HW0	$Cause_{IP2}$ and $Status_{IM2}$	2
Lowest Priority	Software	SW1	$Cause_{IP1}$ and $Status_{IM1}$	1
		SW0	$Cause_{IP0}$ and $Status_{IM0}$	0

The priority order places a relative priority on each hardware interrupt and places the software interrupts at a priority lower than all hardware interrupts. When the priority encoder finds the highest priority pending interrupt, it outputs an encoded vector number that is used in the calculation of the handler for that interrupt, as described below. This is shown pictorially in [Figure 6.1](#).

Figure 6.1 Interrupt Generation for Vectored Interrupt Mode

Note that an interrupt request may be deasserted between the time the processor detects the interrupt request and the time that the software interrupt handler runs. The software interrupt handler must be prepared to handle this condition by simply returning from the interrupt via ERET.

A typical software handler for vectored interrupt mode bypasses the entire sequence of code following the IVexception label shown for the compatibility mode handler above. Instead, the hardware performs the prioritization, dispatching directly to the interrupt processing routine. Unlike the compatibility mode examples, a vectored interrupt handler may take advantage of a dedicated GPR shadow set to avoid saving any registers. As such, the SimpleInterrupt code shown above need not save the GPRs.

A nested interrupt is similar to that shown for compatibility mode, but may also take advantage of running the nested exception routine in the GPR shadow set dedicated to the interrupt or in another shadow set. Such a routine might look as follows:

```
NestedException:
/*
 * Nested exceptions typically require saving the EPC, Status and SRSSctl registers,
 * setting up the appropriate GPR shadow set for the routine, disabling
 * the appropriate IM bits in Status to prevent an interrupt loop, putting
 * the processor in kernel mode, and re-enabling interrupts. The sample code
 * below cannot cover all nuances of this processing and is intended only
 * to demonstrate the concepts.
 */

/* Use the current GPR shadow set, and setup software context */
dmfc0 k0, C0_EPC          /* Get restart address */
sd    k0, EPCSave         /* Save in memory */
mfc0  k0, C0_Status       /* Get Status value */
```

Interrupts and Exceptions

```
sw      k0, StatusSave      /* Save in memory */
mfc0    k0, C0_SRSCtl       /* Save SRSCtl if changing shadow sets */
sw      k0, SRSCtlSave
li      k1, ~IMbitsToClear  /* Get Im bits to clear for this interrupt */
/*      this must include at least the IM bit */
/*      for the current interrupt, and may include */
/*      others */
and     k0, k0, k1          /* Clear bits in copy of Status */
/* If switching shadow sets, write new value to SRSCtl_PSS here */
ins     k0, zero, S_StatusEXL, (W_StatusKSU+W_StatusERL+W_StatusEXL)
/* Clear KSU, ERL, EXL bits in k0 */
mtc0    k0, C0_Status       /* Modify mask, switch to kernel mode, */
/*      re-enable interrupts */

/*
 * If switching shadow sets, clear only KSU above, write target
 * address to EPC, and do execute an eret to clear EXL, switch
 * shadow sets, and jump to routine
 */

/* Process interrupt here, including clearing device interrupt */

/*
 * To complete interrupt processing, the saved values must be restored
 * and the original interrupted code restarted.
 */

di      /* Disable interrupts - may not be required */
lw      k0, StatusSave      /* Get saved Status (including EXL set) */
ld      k1, EPCSave         /* and EPC */
mtc0    k0, C0_Status       /* Restore the original value */
lw      k0, SRSCtlSave      /* Get saved SRSCtl */
dmtc0   k1, C0_EPC         /* and EPC */
mtc0    k0, C0_SRSCtl       /* Restore shadow sets */
ehb     /* Clear hazard */
eret    /* Dismiss the interrupt */
```

6.1.1.3 External Interrupt Controller Mode

External Interrupt Controller Mode redefines the way that the processor interrupt logic is configured to provide support for an external interrupt controller. The interrupt controller is responsible for prioritizing all interrupts, including hardware, software, timer, and performance counter interrupts, and directly supplying to the processor the vector number (and optionally the priority level) of the highest priority interrupt. EIC interrupt mode is in effect if all of the following conditions are true:

- $Config3_{VEIC} = 1$
- $IntCtl_{VS} \neq 0$
- $Cause_{IV} = 1$
- $Status_{BEV} = 0$

In EIC interrupt mode, the processor sends the state of the software interrupt requests ($Cause_{IPL..IP0}$), the timer interrupt request ($Cause_{TI}$), and the performance counter interrupt request ($Cause_{PCI}$) to the external interrupt controller, where it prioritizes these interrupts in a system-dependent way with other hardware interrupts. The interrupt control-

ler can be a hard-wired logic block, or it can be configurable based on control and status registers. This allows the interrupt controller to be more specific or more general as a function of the system environment and needs.

The external interrupt controller prioritizes its interrupt requests and produces the priority level and the vector number of the highest priority interrupt to be serviced. The priority level, called the Requested Interrupt Priority Level (RIPL), is a 6-bit encoded value in the range 0..63, inclusive. A value of 0 indicates that no interrupt requests are pending. The values 1..63 represent the lowest (1) to highest (63) RIPL for the interrupt to be serviced. The interrupt controller passes this value on the 6 hardware interrupt lines, which are treated as an encoded value in EIC interrupt mode. There are several implementation options available for the vector offset:

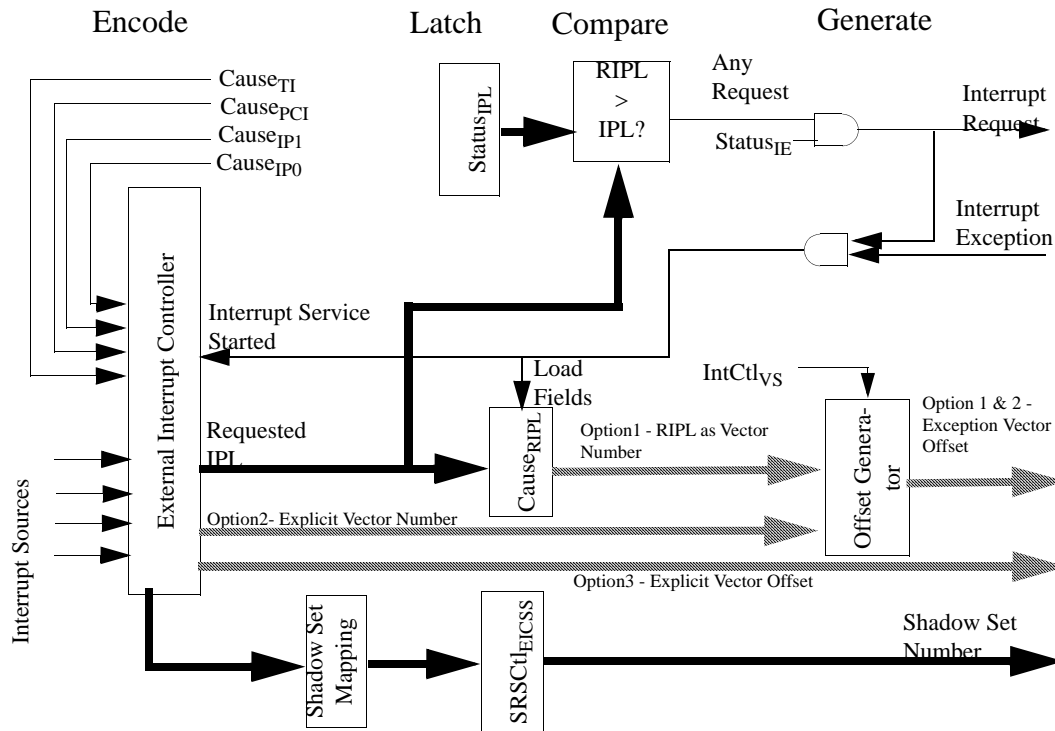

1. The first option is to treat the RIPL value as the vector number for the processor.
2. The second option is to send a separate vector number along with the RIPL to the processor.
3. A third option is to send an entire vector offset along with the RIPL to the processor.

$Status_{IPL}$ (which overlays $Status_{IM7..IM2}$) is interpreted as the Interrupt Priority Level (IPL) at which the processor is currently operating (with a value of zero indicating that no interrupt is currently being serviced). When the interrupt controller requests service for an interrupt, the processor compares RIPL with $Status_{IPL}$ to determine if the requested interrupt has higher priority than the current IPL. If RIPL is strictly greater than $Status_{IPL}$, and interrupts are enabled ($Status_{IE} = 1$, $Status_{EXL} = 0$, and $Status_{ERL} = 0$) an interrupt request is signaled to the pipeline. When the processor starts the interrupt exception, it loads RIPL into $Cause_{RIPL}$ (which overlays $Cause_{IP7..IP2}$) and signals the external interrupt controller to notify it that the request is being serviced. Because $Cause_{RIPL}$ is only loaded by the processor when an interrupt exception is signaled, it is available to software during interrupt processing. The vector number that the EIC passes into the core is combined with the $IntCtl_{VS}$ to determine where the interrupt service routines is located. The vector number is not stored in any software visible register. Some implementations may choose to use the RIPL as the vector number, but this is not a requirement.

In EIC interrupt mode, the external interrupt controller is also responsible for supplying the GPR shadow set number to use when servicing the interrupt. As such, the $SRSMap$ register is not used in this mode, and the mapping of the vectored interrupt to a GPR shadow set is done by programming (or designing) the interrupt controller to provide the correct GPR shadow set number when an interrupt is requested. When the processor loads an interrupt request into $Cause_{RIPL}$, it also loads the GPR shadow set number into $SRSCtl_{EICSS}$, which is copied to $SRSCtl_{CSS}$ when the interrupt is serviced.

The operation of EIC interrupt mode is shown pictorially in [Figure 6.2](#).

Figure 6.2 Interrupt Generation for External Interrupt Controller Interrupt Mode

A typical software handler for EIC interrupt mode bypasses the entire sequence of code following the IVexception label shown for the compatibility mode handler above. Instead, the hardware performs the prioritization, dispatching directly to the interrupt processing routine. Unlike the compatibility mode examples, an EIC interrupt handler may take advantage of a dedicated GPR shadow set to avoid saving any registers. As such, the SimpleInterrupt code shown above need not save the GPRs.

A nested interrupt is similar to that shown for compatibility mode, but may also take advantage of running the nested exception routine in the GPR shadow set dedicated to the interrupt or in another shadow set. It also need only copy *CauseRIPL* to *StatusIPL* to prevent lower priority interrupts from interrupting the handler. Such a routine might look as follows:

```
NestedException:
/*
 * Nested exceptions typically require saving the EPC, Status, and SRSCtl registers,
 * setting up the appropriate GPR shadow set for the routine, disabling
 * the appropriate IM bits in Status to prevent an interrupt loop, putting
 * the processor in kernel mode, and re-enabling interrupts. The sample code
 * below cannot cover all nuances of this processing and is intended only
 * to demonstrate the concepts.
 */

/* Use the current GPR shadow set, and setup software context */
mfc0 k1, C0_Cause /* Read Cause to get RIPL value */
dmfc0 k0, C0_EPC /* Get restart address */
srl k1, k1, S_CauseRIPL /* Right justify RIPL field */
sd k0, EPCSave /* Save in memory */
mfc0 k0, C0_Status /* Get Status value */
```

```

sw      k0, StatusSave      /* Save in memory */
ins     k0, k1, S_StatusIPL, 6 /* Set IPL to RIPL in copy of Status */
mfc0    k1, C0_SRSCtl       /* Save SRSCtl if changing shadow sets */
sw      k1, SRSCtlSave
/* If switching shadow sets, write new value to SRSCtlpgs here */
ins     k0, zero, S_StatusEXL, (W_StatusKSU+W_StatusERL+W_StatusEXL)
/* Clear KSU, ERL, EXL bits in k0 */
mtc0    k0, C0_Status       /* Modify IPL, switch to kernel mode, */
/* re-enable interrupts */

/*
 * If switching shadow sets, clear only KSU above, write target
 * address to EPC, and do execute an eret to clear EXL, switch
 * shadow sets, and jump to routine
 */

/* Process interrupt here, including clearing device interrupt */

/*
 * The interrupt completion code is identical to that shown for VI mode above.
 */

```

6.1.2 Generation of Exception Vector Offsets for Vectored Interrupts

For vectored interrupts (in either VI or EIC interrupt mode - options 1 & 2), a vector number is produced by the interrupt control logic. This number is combined with $IntCtl_{VS}$ to create the interrupt offset, which is added to 0x200 to create the exception vector offset. For VI interrupt mode, the vector number is in the range 0..7, inclusive. For EIC interrupt mode, the vector number is in the range 1..63, inclusive (0 being the encoding for “no interrupt”). The $IntCtl_{VS}$ field specifies the spacing between vector locations. If this value is zero (the default reset state), the vector spacing is zero and the processor reverts to Interrupt Compatibility Mode. A non-zero value enables vectored interrupts, and Table 6.4 shows the exception vector offset for a representative subset of the vector numbers and values of the $IntCtl_{VS}$ field.

Table 6.4 Exception Vector Offsets for Vectored Interrupts

Vector Number	Value of $IntCtl_{VS}$ Field				
	0b00001	0b00010	0b00100	0b01000	0b10000
0	0x0200	0x0200	0x0200	0x0200	0x0200
1	0x0220	0x0240	0x0280	0x0300	0x0400
2	0x0240	0x0280	0x0300	0x0400	0x0600
3	0x0260	0x02C0	0x0380	0x0500	0x0800
4	0x0280	0x0300	0x0400	0x0600	0x0A00
5	0x02A0	0x0340	0x0480	0x0700	0x0C00
6	0x02C0	0x0380	0x0500	0x0800	0x0E00
7	0x02E0	0x03C0	0x0580	0x0900	0x1000
⋮					
61	0x09A0	0x1140	0x2080	0x3F00	0x7C00
62	0x09C0	0x1180	0x2100	0x4000	0x7E00
63	0x09E0	0x11C0	0x2180	0x4100	0x8000

The general equation for the exception vector offset for a vectored interrupt is:

$$\text{vectorOffset} \leftarrow 0x200 + (\text{vectorNumber} \times (\text{IntCtl}_{\text{VS}} \parallel 0b00000))$$

6.1.2.1 Software Hazards and the Interrupt System

Software writes to certain coprocessor 0 register fields may change the conditions under which an interrupt is taken. This creates a coprocessor 0 (CP0) hazard, as described in the chapter “CP0 Hazards” on page 121. In Release 1 of the Architecture, there was no architecturally-defined method for bounding the number of instructions which would be executed after the instruction which caused the interrupt state change and before the change to the interrupt state was seen. In Release 2 of the Architecture, the EHB instruction was added, and this instruction can be used by software to clear the hazard.

Table 6.5 lists the CP0 register fields which can cause a change to the interrupt state (either enabling interrupts which were previously disabled or disabling interrupts which were previously enabled).

Table 6.5 Interrupt State Changes Made Visible by EHB

Instruction(s)	CP0 Register Written	CP0 Register Field(s) Modified
MTC0	Status	IM, IPL, ERL, EXL, IE
EI, DI	Status	IE
MTC0	Cause	IP _{1..0}
MTC0	PerfCnt Control	IE
MTC0	PerfCnt Counter	Event Count

An EHB, executed after one of these fields is modified by the listed instruction, makes the change to the interrupt state visible no later than the instruction following the EHB.

In the following example, a change to the Cause_{IM} field is made visible by an EHB:

```
mfc0    k0, C0_Status
ins     k0, zero, S_StatusIM4, 1      /* Clear bit 4 of the IM field */
mtc0    k0, C0_Status                /* Re-write the register */
ehb                                /* Clear the hazard */
/* Change to the interrupt state is seen no later than this instruction */
```

Similarly, the effects of an DI instruction are made visible by an EHB:

```
di                                /* Disable interrupts */
ehb                                /* Clear the hazard */
/* Change to the interrupt state is seen no later than this instruction */
```

6.2 Exceptions

Normal execution of instructions may be interrupted when an exception occurs. Such events can be generated as a by-product of instruction execution (e.g., an integer overflow caused by an add instruction or a TLB miss caused by a load instruction), or by an event not directly related to instruction execution (e.g., an external interrupt). When an exception occurs, the processor stops processing instructions, saves sufficient state to resume the interrupted instruction stream, enters Kernel Mode, and starts a software exception handler. The saved state and the address of the software exception handler are a function of both the type of exception, and the current state of the processor.

6.2.1 Exception Priority

Table 6.6 lists all possible exceptions, and the relative priority of each, highest to lowest.

Table 6.6 Priority of Exceptions

Exception	Description	Type
Reset	The Cold Reset signal was asserted to the processor	Asynchronous Reset
Soft Reset	The Reset signal was asserted to the processor	
Debug Single Step	An EJTAG Single Step occurred. Prioritized above other exceptions, including asynchronous exceptions, so that one can single-step into interrupt (or other asynchronous) handlers.	Synchronous Debug
Debug Interrupt	An EJTAG interrupt (EjtagBrk or DINT) was asserted.	Asynchronous Debug
Imprecise Debug Data Break	An imprecise EJTAG data break condition was asserted.	
Nonmaskable Interrupt (NMI)	The NMI signal was asserted to the processor.	Asynchronous
Machine Check	An internal inconsistency was detected by the processor.	
Interrupt	An enabled interrupt occurred.	
Deferred Watch	A watch exception, deferred because <i>EXL</i> was one when the exception was detected, was asserted after <i>EXL</i> went to zero.	
Debug Instruction Break	An EJTAG instruction break condition was asserted. Prioritized above instruction fetch exceptions to allow break on illegal instruction addresses.	Synchronous Debug
Watch - Instruction fetch	A watch address match was detected on an instruction fetch. Prioritized above instruction fetch exceptions to allow watch on illegal instruction addresses.	Synchronous
Address Error - Instruction fetch	A non-word-aligned address was loaded into PC.	
TLB/XTLB Refill - Instruction fetch	A TLB miss occurred on an instruction fetch.	
TLB Invalid - Instruction fetch	The valid bit was zero in the TLB entry mapping the address referenced by an instruction fetch.	
TLB Execute-Inhibit	An instruction fetch matched a valid TLB entry which had the XI bit set.	
Cache Error - Instruction fetch	A cache error occurred on an instruction fetch.	
Bus Error - Instruction fetch	A bus error occurred on an instruction fetch.	Synchronous Debug
SDBBP	An EJTAG SDBBP instruction was executed.	
Instruction Validity Exceptions	An instruction could not be completed because it was not allowed access to the required resources, or was illegal: Coprocessor Unusable, MDMX Unusable, Reserved Instruction. If any two exceptions occur on the same instruction, the Coprocessor Unusable and MDMX Unusable Exceptions take priority over the Reserved Instruction Exception.	Synchronous
Execution Exception	An instruction-based exception occurred: Integer overflow, trap, system call, breakpoint, floating-point, coprocessor 2 exception.	
Precise Debug Data Break	A precise EJTAG data break on load/store (address match only) or a data break on store (address+data match) condition was asserted. Prioritized above data fetch exceptions to allow break on illegal data addresses.	Synchronous Debug

Table 6.6 Priority of Exceptions (Continued)

Exception	Description	Type
Watch - Data access	A watch address match was detected on the address referenced by a load or store. Prioritized above data fetch exceptions to allow watch on illegal data addresses.	Synchronous
Address error - Data access	An unaligned address, or an address that was inaccessible in the current processor mode was referenced, by a load or store instruction	
TLB/XTLB Refill - Data access	A TLB miss occurred on a data access	
TLB Invalid - Data access	The valid bit was zero in the TLB entry mapping the address referenced by a load or store instruction	
TLB Read-Inhibit	A data read access matched a valid TLB entry whose RI bit is set.	
TLB Modified - Data access	The dirty bit was zero in the TLB entry mapping the address referenced by a store instruction	
Cache Error - Data access	A cache error occurred on a load or store data reference	Synchronous or Asynchronous
Bus Error - Data access	A bus error occurred on a load or store data reference	

The “Type” column of [Table 6.7](#) describes the type of exception. [Table 6.8](#) explains the characteristics of each exception type.

Table 6.7 Exception Type Characteristics

Exception Type	Characteristics
Asynchronous Reset	Denotes a reset-type exception that occurs asynchronously to instruction execution. These exceptions always have the highest priority to guarantee that the processor can always be placed in a runnable state.
Asynchronous Debug	Denotes an EJTAG debug exception that occurs asynchronously to instruction execution. These exceptions have very high priority with respect to other exceptions because of the desire to enter Debug Mode, even in the presence of other exceptions, both asynchronous and synchronous.
Asynchronous	Denotes any other type of exception that occurs asynchronously to instruction execution. These exceptions are shown with higher priority than synchronous exceptions mainly for notational convenience. If one thinks of asynchronous exceptions as occurring between instructions, they are either the lowest priority relative to the previous instruction, or the highest priority relative to the next instruction. The ordering of the table above considers them in the second way.
Synchronous Debug	Denotes an EJTAG debug exception that occurs as a result of instruction execution, and is reported precisely with respect to the instruction that caused the exception. These exceptions are prioritized above other synchronous exceptions to allow entry to Debug Mode, even in the presence of other exceptions.
Synchronous	Denotes any other exception that occurs as a result of instruction execution, and is reported precisely with respect to the instruction that caused the exception. These exceptions tend to be prioritized below other types of exceptions, but there is a relative priority of synchronous exceptions with each other.

6.2.2 Exception Vector Locations

The Reset, Soft Reset, and NMI exceptions are always vectored to location `0xFFFF.FFFF.BFC0.0000`. EJTAG Debug exceptions are vectored to location `0xFFFF.FFFF.BFC0.0480`, or to location `0xFFFF.FFFF.FF20.0200` if the ProbTrap bit is zero or one, respectively, in the EJTAG_Control_register.

Addresses for all other exceptions are a combination of a vector offset and a vector base address. In Release 1 of the architecture, the vector base address was fixed. In Release 2 of the architecture (and subsequent releases), software is allowed to specify the vector base address via the *EBase* register for exceptions that occur when *Status_{BEV}* equals 0. Table 6.8 gives the vector base address as a function of the exception and whether the *BEV* bit is set in the *Status* register. Table 6.9 gives the offsets from the vector base address as a function of the exception. Note that the *IV* bit in the *Cause* register causes Interrupts to use a dedicated exception vector offset, rather than the general exception vector. For implementations of Release 2 of the Architecture (and subsequent releases), Table 6.4 gives the offset from the base address in the case where *Status_{BEV}* = 0 and *Cause_{IV}* = 1. For implementations of Release 1 of the architecture in which *Cause_{IV}* = 1, the vector offset is as if *IntCtl_{VS}* were 0.

Table 6.10 combines these two tables into one that contains all possible vector addresses as a function of the state that can affect the vector selection. To avoid complexity in the table, the vector address value assumes that the *EBase* register, as implemented in Release 2 devices, is not changed from its reset state and that *IntCtl_{VS}* is 0.

In Release 2 of the Architecture (and subsequent releases), software must guarantee that *EBase_{15..12}* contains zeros in all bit positions less than or equal to the most significant bit in the vector offset. This situation can only occur when a vector offset greater than 0xFFF is generated when an interrupt occurs with VI or EIC interrupt mode enabled. The operation of the processor is **UNDEFINED** if this condition is not met.

Table 6.8 Exception Vector Base Addresses

Exception	<i>Status_{BEV}</i>	
	0	1
Reset, Soft Reset, NMI	0xFFFF.FFFF.BFC0.0000	
EJTAG Debug (with ProbTrap = 0 in the EJTAG_Control_register)	0xFFFF.FFFF.BFC0.0480	
EJTAG Debug (with ProbTrap = 1 in the EJTAG_Control_register)	0xFFFF.FFFF.FF20.0200	
Cache Error	<i>For Release 1 of the architecture:</i> 0xFFFF.FFFF.A000.0000 <i>For Release 2 of the architecture:</i> 0xFFFF.FFFF <i>EBase_{31..30}</i> 1 <i>EBase_{28..12}</i> 0x000 Note that <i>EBase_{31..30}</i> have the fixed value 0b10	0xFFFF.FFFF.BFC0.0200
Other	<i>For Release 1 of the architecture:</i> 0xFFFF.FFFF.8000.0000 <i>For Release 2 of the architecture:</i> 0xFFFF.FFFF <i>EBase_{31..12}</i> 0x000 Note that <i>EBase_{31..30}</i> have the fixed value 0b10	0xFFFF.FFFF.BFC0.0200

Table 6.9 Exception Vector Offsets

Exception	Vector Offset
TLB Refill, <i>EXL</i> = 0	0x000

Table 6.9 Exception Vector Offsets (Continued)

Exception	Vector Offset
64-bit XTLB Refill, EXL = 0	0x080
Cache error	0x100
General Exception	0x180
Interrupt, $Cause_{IV} = 1$	0x200 (In Release 2 implementations, this is the base of the vectored interrupt table when $Status_{BEV} = 0$)
Reset, Soft Reset, NMI	None (Uses Reset Base Address)

Table 6.10 Exception Vectors

Exception	$Status_{BEV}$	$Status_{EXL}$	$Cause_{IV}$	EJTAG ProbTrap	Vector For Release 2 Implementations, assumes that EBase retains its reset state and that $IntCtl_{VS} = 0$
Reset, Soft Reset, NMI	x	x	x	x	0xFFFF.FFFF.BFC0.0000
EJTAG Debug	x	x	x	0	0xFFFF.FFFF.BFC0.0480
EJTAG Debug	x	x	x	1	0xFFFF.FFFF.FF20.0200

Interrupt	0	0	1	x	0xFFFF.FFFF.8000.0200
Interrupt	1	0	0	x	0xFFFF.FFFF.BFC0.0380
Interrupt	1	0	1	x	0xFFFF.FFFF.BFC0.0400
All others	0	x	x	x	0xFFFF.FFFF.8000.0180
All others	1	x	x	x	0xFFFF.FFFF.BFC0.0380
'x' denotes don't care					

6.2.3 General Exception Processing

With the exception of Reset, Soft Reset, NMI, cache error, and EJTAG Debug exceptions, which have their own special processing as described below, exceptions have the same basic processing flow:

- If the *EXL* bit in the *Status* register is zero, the *EPC* register is loaded with the PC at which execution will be restarted and the *BD* bit is set appropriately in the *Cause* register (see Table 9.55 on page 235). The value loaded into the *EPC* register is dependent on whether the processor implements the MIPS16 ASE, and whether the instruction is in the delay slot of a branch or jump which has delay slots. Table 6.11 shows the value stored in each of the CP0 PC registers, including *EPC*. For implementations of Release 2 of the Architecture if *Status_{BEV}* = 0, the *CSS* field in the *SRSCtl* register is copied to the *PSS* field, and the *CSS* value is loaded from the appropriate source.

If the *EXL* bit in the *Status* register is set, the *EPC* register is not loaded and the *BD* bit is not changed in the *Cause* register. For implementations of Release 2 of the Architecture, the *SRSCtl* register is not changed.

Table 6.11 Value Stored in EPC, ErrorEPC, or DEPC on an Exception

MIPS16 Implemented?	In Branch/Jump Delay Slot?	Value stored in EPC/ErrorEPC/DEPC
No	No	Address of the instruction
No	Yes	Address of the branch or jump instruction (PC-4)
Yes	No	Upper 63 bits of the address of the instruction, combined with the <i>ISA Mode</i> bit
Yes	Yes	Upper 63 bits of the branch or jump instruction (PC-2 in the MIPS16 ISA Mode and PC-4 in the 32-bit ISA Mode), combined with the <i>ISA Mode</i> bit

- The *CE*, and *ExcCode* fields of the *Cause* registers are loaded with the values appropriate to the exception. The *CE* field is loaded, but not defined, for any exception type other than a coprocessor unusable exception.
- The *EXL* bit is set in the *Status* register.
- The processor is started at the exception vector.

The value loaded into *EPC* represents the restart address for the exception and need not be modified by exception handler software in the normal case. Software need not look at the *BD* bit in the *Cause* register unless it wishes to identify the address of the instruction that actually caused the exception.

Note that individual exception types may load additional information into other registers. This is noted in the description of each exception type below.

Operation:

```

/* If StatusEXL is 1, all exceptions go through the general exception vector */
/* and neither EPC nor CauseBD nor SRSCtl are modified */
if StatusEXL = 1 then
    vectorOffset ← 0x180
else
    if InstructionInBranchDelaySlot then
        EPC ← restartPC /* PC of branch/jump */
        CauseBD ← 1
    else
        EPC ← restartPC /* PC of instruction */
        CauseBD ← 0
    endif
endif

```

Interrupts and Exceptions

    endif
endif
endif

```

```

/* Exception PC is the sum of vectorBase and vectorOffset. Vector */
/* offsets > 0xFFFF (vectored or EIC interrupts only), require */
/* that EBase15..12 have zeros in each bit position less than or */
/* equal to the most significant bit position of the vector offset */
PC ← vectorBase63..30 || (vectorBase29..0 + vectorOffset29..0)
/* No carry between bits 29 and 30 */

```

6.2.4 EJTAG Debug Exception

An EJTAG Debug Exception occurs when one of a number of EJTAG-related conditions is met. Refer to the EJTAG Specification for details of this exception.

Entry Vector Used

0xFFFF FFFF BFC0 0480 if the *ProbTrap* bit is zero in the *EJTAG_Control_register*; 0xFFFF FFFF FF20 0200 if the *ProbTrap* bit is one.

6.2.5 Reset Exception

A Reset Exception occurs when the Cold Reset signal is asserted to the processor. This exception is not maskable. When a Reset Exception occurs, the processor performs a full reset initialization, including aborting state machines, establishing critical state, and generally placing the processor in a state in which it can execute instructions from uncached, unmapped address space. On a Reset Exception, only the following registers have defined state:

- The *Random* register is initialized to the number of TLB entries minus one. The Random register is deprecated in Release 6.
- The *Wired* register is initialized to zero.
- The *Config*, *Config1*, *Config2*, and *Config3* registers are initialized with their boot state.
- The *RP*, *BEV*, *TS*, *SR*, *NMI*, and *ERL* fields of the *Status* register are initialized to a specified state.
- *Watch* register enables and *Performance Counter* register interrupt enables are cleared.
- The *ErrorEPC* register is loaded with the restart PC, as described in [Table 6.11](#). Note that this value may or may not be predictable if the Reset Exception was taken as the result of power being applied to the processor because PC may not have a valid value in that case. In some implementations, the value loaded into *ErrorEPC* register may not be predictable on either a Reset or Soft Reset Exception.
- PC is loaded with 0xFFFF FFFF BFC0 0000.

6.2.6 Soft Reset Exception

A Soft Reset Exception occurs when the Reset signal is asserted to the processor. This exception is not maskable. When a Soft Reset Exception occurs, the processor performs a subset of the full reset initialization. Although a Soft Reset Exception does not unnecessarily change the state of the processor, it may be forced to do so in order to place the processor in a state in which it can execute instructions from uncached, unmapped address space. Since bus, cache, or other operations may be interrupted, portions of the cache, memory, or other processor state may be inconsistent.

The primary difference between the Reset and Soft Reset Exceptions is in actual use. The Reset Exception is typically used to initialize the processor on power-up, while the Soft Reset Exception is typically used to recover from a non-responsive (hung) processor. The semantic difference is provided to allow boot software to save critical coprocessor 0 or other register state to assist in debugging the potential problem. As such, the processor may reset the same state when either reset signal is asserted, but the interpretation of any state saved by software may be very different.

In addition to any hardware initialization required, the following state is established on a Soft Reset Exception:

- The *RP*, *BEV*, *TS*, *SR*, *NMI*, and *ERL* fields of the *Status* register are initialized to a specified state.

- *Watch* register enables and *Performance Counter* register interrupt enables are cleared.
- The *ErrorEPC* register is loaded with the restart PC, as described in [Table 6.11](#). Note that this value may or may not be predictable.
- PC is loaded with 0xFFFF FFFF BFC0 0000.

```

6.2.7 Non Maskable Interrupt (NMI) Exception

A non maskable interrupt exception occurs when the NMI signal is asserted to the processor.

Although described as an interrupt, it is more correctly described as an exception because it is not maskable. An NMI occurs only at instruction boundaries, so does not do any reset or other hardware initialization. The state of the cache, memory, and other processor state is consistent and all registers are preserved, with the following exceptions:

- The *BEV*, *TS*, *SR*, *NMI*, and *ERL* fields of the *Status* register are initialized to a specified state.
- The *ErrorEPC* register is loaded with restart PC, as described in [Table 6.11](#).
- PC is loaded with 0xFFFF FFFF BFC0 0000.

6.2.8 Machine Check Exception

A machine check exception occurs when the processor detects an internal inconsistency.

The following conditions cause a machine check exception:

- Detection of multiple matching entries in the TLB in a TLB-based MMU. If the Hardware Page Table Walker feature is implemented and the Directory-level Huge page feature is supported and the Dual Page method is also supported, and if the first accessed PTE entry has PTEVld bit set and the second accessed PTE entry has PTEVld bit clear.

Cause Register ExcCode Value

MCheck (See [Table 9.56 on page 238](#))

Additional State Saved

Depends on the condition that caused the exception. See the descriptions above.

If there are multiple causes for the machine check exception, then the *PageGrain*_{MCCause} register field is used to distinguish which condition caused the exception.

Entry Vector Used

General exception vector (offset 0x180)

6.2.9 Address Error Exception

An address error exception occurs under the following circumstances:

- A load or store doubleword instruction is executed in which the address is not aligned on a doubleword boundary.

- An instruction is fetched from an address that is not aligned on a word boundary.
- A load or store word instruction is executed in which the address is not aligned on a word boundary.
- A load or store halfword instruction is executed in which the address is not aligned on a halfword boundary.
- A reference is made to a kernel address space from User Mode or Supervisor Mode.
- A reference is made to a supervisor address space from User Mode.
- A reference is made to a 64-bit address that is outside the range of the 32-bit Compatibility Address Space when 64-bit address references are not enabled.
- A reference is made to an undefined or unimplemented 64-bit address when 64-bit address references are enabled.

Release 6 supports misaligned load/store handling. Whether an Address Error is generated is implementation-dependent, as described in Appendix B of *Volume I-A* of the MIPS Architecture documentation set.

Note that in the case of an instruction fetch that is not aligned on a word boundary, the PC is updated before the condition is detected. Therefore, both *EPC* and *BadVAddr* point at the unaligned instruction address.

6.2.10 TLB Refill and XTLB Refill Exceptions

A TLB Refill or XTLB Refill exception occurs in a TLB-based MMU when no TLB entry matches a reference to a mapped address space and the *EXL* bit is zero in the *Status* register. Note that this is distinct from the case in which an entry matches but has the valid bit off, in which case a TLB Invalid exception occurs. Refill exceptions have distinct

Interrupts and Exceptions

exception vector offsets: 0x000 for a 32-bit TLB Refill and 0x080 for a 64-bit extended TLB (“XTLB”) refill. The XTLB refill handler is used whenever a reference is made to an enabled 64-bit address space.

6.2.13 TLB Invalid Exception

A TLB invalid exception occurs when a TLB entry matches a reference to a mapped address space, but the matched entry has the valid bit off.

Note that the condition in which no TLB entry matches a reference to a mapped address space and the *EXL* bit is one in the *Status* register is indistinguishable from a TLB Invalid Exception, in the sense that both use the general exception vector and supply an ExcCode value of TLBL or TLBS. The only way to distinguish these two cases is by probing the TLB for a matching entry (using TLBP).

If the RI and XI bits are implemented within the TLB and the *PageGrain_{IEC}* bit is clear, then this exception also occurs if a valid, matching TLB entry is found with the RI bit set on a memory load reference, or with the XI bit set on an instruction fetch memory reference. MIPS16 PC-relative loads are a special case and are not affected by the RI bit.

6.2.21 Reserved Instruction Exception

A Reserved Instruction Exception occurs if any of the following conditions is true:

- An instruction was executed that specifies an encoding of the opcode field that is flagged with “*” (reserved), “β” (higher-order ISA), “⊥” (64-bit) if 64-bit operations are not enabled, or an unimplemented “ε” (Module/ASE).
- An instruction was executed that specifies a *SPECIAL* opcode encoding of the function field that is flagged with “*” (reserved), “β” (higher-order ISA), or “⊥” (64-bit) if 64-bit operations are not enabled.
- An instruction was executed that specifies a *REGIMM* opcode encoding of the rt field that is flagged with “*” (reserved).
- An instruction was executed that specifies an unimplemented *SPECIAL2* opcode encoding of the function field that is flagged with an unimplemented “θ” (partner available), “⊥” (64-bit) if 64-bit operations are not enabled, or an unimplemented “σ” (EJTAG).
- An instruction was executed that specifies a *COPz* opcode encoding of the rs field that is flagged with “*” (reserved), “β” (higher-order ISA), “⊥” (64-bit) if 64-bit operations are not enabled, or an unimplemented “ε” (Module/ASE), assuming that access to the coprocessor is allowed. If access to the coprocessor is not allowed, a Coprocessor Unusable Exception occurs instead. For the *COP1* opcode, some implementations of previous ISAs reported this case as a Floating-Point Exception, setting the Unimplemented Operation bit in the Cause field of the *FCSR* register.
- An instruction was executed that specifies an unimplemented *COP0* opcode encoding of the function field when rs is CO that is flagged with “*” (reserved), or an unimplemented “σ” (EJTAG), assuming that access to coprocessor 0 is allowed. If access to the coprocessor is not allowed, a Coprocessor Unusable Exception occurs instead.
- An instruction was executed that specifies a *COP1* opcode encoding of the function field when rs is S, D, or W that is flagged with “*” (reserved), “β” (higher-order ISA), “⊥” (64-bit) if 64-bit operations are not enabled, or an unimplemented “ε” (Module/ASE), assuming that access to coprocessor 1 is allowed. If access to the coprocessor is not allowed, a Coprocessor Unusable Exception occurs instead. Some implementations of previous ISAs reported this case as a Floating-Point Exception, setting the Unimplemented Operation bit in the Cause field of the *FCSR* register.
- An instruction was executed that specifies a *COP1* opcode encoding when rs is L or PS and 64-bit operations are not enabled, or with a function field encoding that is flagged with “*” (reserved), “β” (higher-order ISA), or an unimplemented “ε” (Module/ASE), assuming that access to coprocessor 1 is allowed. If access to the coprocessor is not allowed, a Coprocessor Unusable Exception occurs instead. Some implementations of previous ISAs reported this case as a Floating-Point Exception, setting the Unimplemented Operation bit in the Cause field of the *FCSR* register.
- An instruction was executed that specifies a *COPIX* opcode encoding of the function field that is flagged with “*” (reserved), or any execution of the *COPIX* opcode when 64-bit operations are not enabled, assuming that access to coprocessor 1 is allowed. If access to the coprocessor is not allowed, a Coprocessor Unusable Exception occurs instead. Some implementations of previous ISAs reported this case as a Floating-Point Exception, setting the Unimplemented Operation bit in the Cause field of the *FCSR* register.

Defined by the coprocessor

Entry Vector Used

General exception vector (offset 0x180)

6.2.26 Watch Exception

The watch facility provides a software debugging vehicle by initiating a watch exception when an instruction or data reference matches the address information stored in the *WatchHi* and *WatchLo* registers. A watch exception is taken immediately if the *EXL* and *ERL* bits of the *Status* register are both zero. If either bit is a one at the time that a watch exception would normally be taken, the *WP* bit in the *Cause* register is set, and the exception is deferred until both the *EXL* and *ERL* bits in the *Status* register are zero. Software may use the *WP* bit in the *Cause* register to determine if the *EPC* register points at the instruction that caused the watch exception, or if the exception actually occurred while in kernel mode.

If the *EXL* or *ERL* bits are one in the *Status* register and a single instruction generates both a watch exception (which is deferred by the state of the *EXL* and *ERL* bits) and a lower-priority exception, the lower priority exception is taken.

Watch exceptions are never taken if the processor is executing in Debug Mode. Should a watch register match while the processor is in Debug Mode, the exception is inhibited and the *WP* bit is not changed.

It is implementation-dependent whether a data watch exception is triggered by a prefetch or cache instruction whose address matches the *Watch* register address match conditions. A watch triggered by a SC or SCD instruction does so even if the store would not complete because the *LL* bit is zero.

Register ExcCode ValueWATCH (See [Table 9.55 on page 235](#))

Interrupts and Exceptions

Additional State Saved

Register State	Value
Cause _{WP}	Indicates that the watch exception was deferred until after both <i>Status_{EXL}</i> and <i>Status_{ERL}</i> were zero. This bit directly causes a watch exception, so software must clear this bit as part of the exception handler to prevent a watch exception loop at the end of the current handler execution.

Entry Vector Used

General exception vector (offset 0x180)

6.2.27 Interrupt Exception

The interrupt exception occurs when an enabled request for interrupt service is made. See [Section 6.1 on page 85](#) for more information.

Interrupt vector (offset 0x200) if the *IV* bit in the *Cause* register is one.

GPR Shadow Registers

The capability in this chapter is targeted at removing the need to save and restore GPRs on entry to high priority interrupts or exceptions, and to provide specified processor modes with the same capability. This is done by introducing multiple copies of the GPRs, called *shadow sets*, and allowing privileged software to associate a shadow set with entry to Kernel Mode via an interrupt vector or exception. The normal GPRs are logically considered shadow set zero.

The number of GPR shadow sets is implementation-dependent and may range from one (the normal GPRs) to an architectural maximum of 16. The highest number actually implemented is indicated by the `SRSCtlHSS` field, and all shadow sets between 0 and `SRSCtlHSS`, inclusive must be implemented. If this field is zero, only the normal GPRs are implemented.

7.1 Introduction to Shadow Sets

Shadow sets are new copies of the GPRs that can be substituted for the normal GPRs on entry to Kernel Mode via an interrupt or exception. Once a shadow set is bound to a Kernel Mode entry condition, reference to GPRs work exactly as one would expect, but they are redirected to registers that are dedicated to that condition. Privileged software may need to reference all GPRs in the register file, even specific shadow registers that are not visible in the current mode. The `RDPGPR` and `WRPGPR` instructions are used for this purpose. The `CSS` field of the `SRSCtl` register provides the number of the current shadow register set, and the `PSS` field of the `SRSCtl` register provides the number of the previous shadow register set (that which was current before the last exception or interrupt occurred).

If the processor is operating in VI interrupt mode, binding of a vectored interrupt to a shadow set is done by writing to the `SRSSMap` register. If the processor is operating in EIC interrupt mode, the binding of the interrupt to a specific shadow set is provided by the external interrupt controller, and is configured in an implementation-dependent way. Binding of an exception or non-vectored interrupt to a shadow set is done by writing to the `ESS` field of the `SRSCtl` register. When an exception or interrupt occurs, the value of `SRSCtlCSS` is copied to `SRSCtlPSS`, and `SRSCtlCSS` is set to the value taken from the appropriate source. On an `ERET`, the value of `SRSCtlPSS` is copied back into `SRSCtlCSS` to restore the shadow set of the mode to which control returns. More precisely, the rules for updating the fields in the `SRSCtl` register on an interrupt or exception are as follows:

1. No field in the `SRSCtl` register is updated if any of the following conditions are true. In this case, steps 2 and 3 are skipped.
 - The exception is one that sets `StatusERL`: NMI or cache error.
 - The exception causes entry into EJTAG Debug Mode
 - `StatusBEV = 1`
 - `StatusEXL = 1`
2. `SRSCtlCSS` is copied to `SRSCtlPSS`

GPR Shadow Registers

3. $SRSCtl_{CSS}$ is updated from one of the following sources:

- The appropriate field of the $SRSSMap$ register, based on IPL, if the exception is an interrupt, $Cause_{IV} = 1$, $IntCtl_{VSS} \neq 0$, $Config3_{VEIC} = 0$, and $Config3_{VInt} = 1$. These are the conditions for a vectored interrupt.
- The EICSS field of the $SRSCtl$ register if the exception is an interrupt, $Cause_{IV} = 1$, $IntCtl_{VSS} \neq 0$, and $Config3_{VEIC} = 1$. These are the conditions for a vectored EIC interrupt.
- The ESS field of the $SRSCtl$ register in any other case. This is the condition for a non-interrupt exception, or a non-vectored interrupt.

Similarly, the rules for updating the fields in the $SRSCtl$ register at the end of an exception or interrupt are as follows:

1. No field in the $SRSCtl$ register is updated if any of the following conditions is true. In this case, step 2 is skipped.

- A DERET is executed
- An ERET is executed with $Status_{ERL} = 1$ or $Status_{BEV} = 1$

2. $SRSCtl_{PSS}$ is copied to $SRSCtl_{CSS}$

These rules have the effect of preserving the $SRSCtl$ register in any case of a nested exception or one which occurs before the processor has been fully initialize ($Status_{BEV} = 1$).

Privileged software may switch the current shadow set by writing a new value into $SRSCtl_{PSS}$, loading EPC with a target address, and doing an ERET.

7.2 Support Instructions

Table 7.1 Instructions Supporting Shadow Sets

Mnemonic	Function	MIPS64 Only?
RDPGPR	Read GPR From Previous Shadow Set	No
WRPGPR	Write GPR to Shadow Set	No

CP0 Hazards

8.1 Introduction

Because resources controlled via Coprocessor 0 affect the operation of various pipeline stages of a MIPS64/microMIPS64 processor, manipulation of these resources may produce results that are not detectable by subsequent instructions for some number of execution cycles. When no hardware interlock exists between one instruction that causes an effect that is visible to a second instruction, a *CP0 hazard* exists.

In Release 1 of the MIPS64® Architecture, CP0 hazards were relegated to implementation-dependent cycle-based solutions, primarily based on the SSNOP instruction. Since that time, it has become clear that this is an insufficient and error-prone practice that must be addressed with a firm compact between hardware and software. As such, new instructions have been added to Release 2 of the architecture which act as explicit barriers that eliminate hazards. To the extent that it was possible to do so, the new instructions have been added in such a way that they are backward-compatible with existing MIPS processors.

8.2 Types of Hazards

In privileged software, there are two different types of hazards: execution hazards and instruction hazards. Both are defined below.

Implementations using Release 1 of the architecture should refer to their Implementation documentation for the required instruction “spacing” that is required to eliminate these hazards.

Note that, for superscalar MIPS implementations, the number of instructions issued per cycle may be greater than one, and thus that the duration of the hazard in instructions may be greater than the duration in cycles. It is for this reason that MIPS64 Release 1 defines the SSNOP instruction to convert instruction issues to cycles in a superscalar design.

8.2.1 Possible Execution Hazards

Execution hazards are those created by the execution of one instruction, and seen by the execution of another instruction. [Table 8.1](#) lists the possible execution hazards that might exist when there are no hardware interlocks.

Table 8.1 Possible Execution Hazards

Producer	→	Consumer	Hazard On
<i>Hazards Related to the TLB</i>			
MTC0	→	TLBR, TLBWI, TLBWR	EntryHi

Table 8.1 Possible Execution Hazards (Continued)

Producer	→	Consumer	Hazard On
MTC0	→	TLBWI, TLBWR	EntryLo0, EntryLo1, Index, PageMask, PageGrain
MTC0	→	TLBWR	Wired
MTC0	→	TLBP, Load or Store Instruction	EntryHi _{ASID}
MTC0	→	Load/store affected by new state	EntryHi _{ASID} , WatchHi, WatchLo, Config
TLBP	→	MFC0, TLBWI	Index
TLBR	→	MFC0	EntryHi, EntryLo0, EntryLo1, PageMask
TLBWI, TLBWR	→	TLBP, TLBR, Load/store using new TLB entry	TLB entry
<i>Hazards Related to Exceptions or Interrupts</i>			
MTC0	→	Coprocessor instruction execution depends on the new value of Status _{CU}	Status _{CU}
MTC0	→	ERET	DEPC, EPC, ErrorEPC, Status
MTC0	→	Interrupted Instruction	Cause _{IP} , Cause _{IV} , Compare, Count, PerfCnt Control _{IE} , PerfCnt Counter, Status _{IE} , Status _{IM} , EBase, SRSCtl, SRSTMap
EI, DI	→	Interrupted Instruction	Status _{IE} , Status _{IM}
<i>Other Hazards</i>			
LL, LLD	→	MFC0	LLAddr
MTC0	→	CACHE	PageGrain
CACHE	→	MFC0	TagLo

Table 8.1 Possible Execution Hazards (Continued)

Producer	→	Consumer	Hazard On
MTC0	→	MFC0	any CoProcessor 0 register

8.2.2 Possible Instruction Hazards

Instruction hazards are those created by the execution of one instruction, and seen by the instruction fetch of another instruction. [Table 8.2](#) lists the possible instruction hazards when there are no hardware interlocks.

Table 8.2 Possible Instruction Hazards

Producer	→	Consumer	Hazard On
<i>Hazards Related to the TLB</i>			
MTC0	→	Instruction fetch seeing the new value	EntryHi _{ASID} , WatchHi, WatchLo Config
MTC0	→	Instruction fetch seeing the new value (including a change to ERL followed by an instruction fetch from the useg segment)	Status
TLBWI, TLBWR	→	Instruction fetch using new TLB entry	TLB entry
<i>Hazards Related to Writing the Instruction Stream or Modifying an Instruction Cache Entry</i>			
Instruction stream writes	→	Instruction fetch seeing the new instruction stream	Cache entries
CACHE	→	Instruction fetch seeing the new instruction stream	Cache entries
<i>Other Hazards</i>			
MTC0	→	RDPGPR WRPGPR	SRSCtl _{PSS} ¹

1. This is not precisely a hazard on the instruction fetch. Rather it is a hazard on a modification to the previous GPR context field, followed by a previous-context reference to the GPRs. It is considered an instruction hazard rather than an execution hazard because some implementation may require that the previous GPR context be established early in the pipeline, and execution hazards are not meant to cover this case.

8.3 Hazard Clearing Instructions and Events

[Table 8.3](#) lists the instructions designed to eliminate hazards.

Table 8.3 Hazard Clearing Instructions

Mnemonic	Function	Supported Architecture
DERET	Clear both execution and instruction hazards	EJTAG

Table 8.3 Hazard Clearing Instructions (Continued)

Mnemonic	Function	Supported Architecture
EHB	Clear execution hazard	Release 2 onwards
ERET	Clear both execution and instruction hazards	All
IRET	Clear both execution and instruction hazards when not chaining to another interrupt.	MCU ASE
JALR.HB	Clear both execution and instruction hazards	Release 2 onwards
JR.HB	Clear both execution and instruction hazards	Release 2 onwards
SSNOP	Superscalar No Operation	Release 1 onwards
SYNCI ¹	Synchronize caches after instruction stream write	Release 2 onwards

1. SYNCI synchronizes caches after an instruction stream write, and before execution of that instruction stream. As such, it is not precisely a coprocessor 0 hazard, but is included here for completeness.

DERET, ERET, and SSNOP are available in Release 1 of the Architecture; EHB, JALR.HB, JR.HB, and SYNCI were added in Release 2 of the Architecture. In both Release 1 and Release 2 of the Architecture, DERET and ERET clear both execution and instruction hazards and they are the only timing-independent instructions which will do this in both releases of the architecture.

Even though DERET and ERET clear hazards between the execution of the instruction and the target instruction stream, an execution hazard may still be created between a write of the *DEPC*, *EPC*, *ErrorEPC*, or *Status* registers and the DERET or ERET instruction.

In addition, an exception or interrupt also clears both execution and instruction hazards between the instruction that created the hazard and the first instruction of the exception or interrupt handler. Said another way, no hazards remain visible by the first instruction of an exception or interrupt handler.

8.3.1 MIPS64 Instruction Encoding

The EHB instruction is encoded using a variant of the NOP/SSNOP encoding. This encoding was chosen for compatibility with the Release 1 SSNOP instruction, such that existing software may be modified to be compatible with both Release 1 and Release 2 implementations. See the EHB instruction description for additional information.

The JALR.HB and JR.HB instructions are encoding using bit 10 of the *hint* field of the JALR and JR instructions. These encodings were chosen for compatibility with existing MIPS implementations, including many which pre-date the MIPS64 architecture. Because a pipeline flush clears hazards on most early implementations, the JALR.HB or JR.HB instructions can be included in existing software for backward and forward compatibility. See the JALR.HB and JR.HB instructions for additional information.

The SYNCI instruction is encoded using a new encoding of the REGIMM opcode. This encoding was chosen because it causes a Reserved Instruction exception on all Release 1 implementations. As such, kernel software running on processors that don't implement Release 2 can emulate the function using the CACHE instruction.

8.3.2 microMIPS64 Instruction Encoding

The EHB and SSNOP instructions are encoded using a variant of the NOP encoding. See the EHB and SSNOP instruction description for additional information.

Coprocessor 0 Registers

The Coprocessor 0 (CP0) registers provide the interface between the ISA and the PRA. Each register is discussed below, with the registers presented in numerical order, first by register number, then by select field number.

9.1 Coprocessor 0 Register Summary

[Table 9.1](#) lists the CP0 registers in numerical order. The individual registers are described later in this document. If the compliance level is qualified (e.g., “*Required* (TLB MMU)”), it applies only if the qualifying condition is true. The Sel column indicates the value to be used in the field of the same name in the MFC0 and MTC0 instructions.

Table 9.1 Coprocessor 0 Registers in Numerical Order

Register Number	Sel ¹	Register Name	Function	Reference	Compliance Level
0	0	Index	Index into the TLB array	Section 9.4 on page 135	Required (TLB MMU); Optional (Others)
0	1	MVPCControl	Per-processor register containing global MIPS® MT configuration data	MIPS®MT Module Specification	Required (MIPS MT Module); Optional (Others)
0	2	MVPCConf0	Per-processor multi-VPE dynamic configuration information	MIPS®MT Module Specification	Required (MIPS MT Module); Optional (Others)
0	3	MVPCConf1	Per-processor multi-VPE dynamic configuration information	MIPS®MT Module Specification	Optional
1	0	Random	Randomly generated index into the TLB array	Section 9.6 on page 139	Required (TLB MMU) Optional (Others) (Pre-Release 6); Required (Release 6)
1	1	VPEControl	Per-VPE register containing relatively volatile thread configuration data	MIPS®MT Module Specification	Required (MIPS MT Module); Optional (Others)
1	2	VPEConf0	Per-VPE multi-thread configuration information	MIPS®MT Module Specification	Required (MIPS MT Module); Optional (Others)
1	3	VPEConf1	Per-VPE multi-thread configuration information	MIPS®MT Module Specification	Optional
1	4	YQMask	Per-VPE register defining which YIELD qualifier bits may be used without generating an exception	MIPS®MT Module Specification	Required (MIPS MT Module); Optional (Others)

Table 9.1 Coprocessor 0 Registers in Numerical Order (Continued)

Register Number	Sel ¹	Register Name	Function	Reference	Compliance Level
1	5	VPESchedule	Per-VPE register to manage scheduling of a VPE within a processor	MIPS®MT Module Specification	Optional
1	6	VPEScheFBack	Per-VPE register to provide scheduling feedback to software	MIPS®MT Module Specification	Optional
1	7	VPEOpt	Per-VPE register to provide control over optional features, such as cache partitioning control	MIPS®MT Module Specification	Optional
2	0	EntryLo0	Low-order portion of the TLB entry for even-numbered virtual pages	Section 9.7 on page 141	Required (TLB MMU); Optional (Others)
2	1	TCStatus	Per-TC status information, including copies of thread-specific bits of <i>Status</i> and <i>EntryHi</i> registers.	MIPS®MT Module Specification	Required (MIPS MT Module); Optional (Others)
2	2	TCBind	Per-TC information about TC ID and VPE binding	MIPS®MT Module Specification	Required (MIPS MT Module); Optional (Others)
2	3	TCRestart	Per-TC value of restart instruction address for the associated thread of execution	MIPS®MT Module Specification	Required (MIPS MT Module); Optional (Others)
2	4	TCHalt	Per-TC register controlling Halt state of TC	MIPS®MT Module Specification	Required (MIPS MT Module); Optional (Others)
2	5	TCContext	Per-TC read/write storage for operating system use	MIPS®MT Module Specification	Required (MIPS MT Module); Optional (Others)
2	6	TCSchedule	Per-TC register to manage scheduling of a TC	MIPS®MT Module Specification	Optional
2	7	TCScheFBack	Per-TC register to provide scheduling feedback to software	MIPS®MT Module Specification	Optional
3	0	EntryLo1	Low-order portion of the TLB entry for odd-numbered virtual pages	Section 9.7 on page 141	Required (TLB MMU); Optional (Others)
3	7	TCOpt	Per-TC register to provide control over optional features, such as cache partitioning control	MIPS®MT Module Specification	Optional
4	0	Context	Pointer to page table entry in memory	Section 9.9 on page 153	Required (TLB MMU); Optional (Others)
4	1	ContextConfig	Context register configuration	SmartMIPS ASE Specification and Section 9.10 on page 157	Required (SmartMIPS ASE); Optional (Others)
4	2	UserLocal	User information that can be written by privileged software and read via RDHWR register 29. If the processor implements the MIPS® MT Module, this is a per-TC register.	Section 9.11 on page 159	Recommended (Release 2) Required (Release 6)

Table 9.1 Coprocessor 0 Registers in Numerical Order (Continued)

Register Number	Sel ¹	Register Name	Function	Reference	Compliance Level
4	3	XContextConfig	XContext register configuration	Section 9.13 on page 163	Optional
5	0	PageMask	Control for variable page size in TLB entries	Section 9.14 on page 165	Required (TLB MMU); Optional (Others)
5	1	PageGrain	Control for small page support	Section 9.15 on page 169 and SmartMIPS ASE Specification	Required (SmartMIPS ASE); Optional (Release 2)
5	2	SegCtl0	Programmable Control for Segments 0 & 1	Section 9.16 on page 175	Optional
5	3	SegCtl1	Programmable Control for Segments 2 & 3	Section 9.17 on page 175	Optional
5	4	SegCtl2	Programmable Control for Segments 4 & 5	Section 9.18 on page 175	Optional
5	5	PWBase	Page Table Base Address for Hardware Page Walker	Section 9.19 on page 181	Optional
5	6	PWField	Bit indices of pointers for Hardware Page Walker	Section 9.20 on page 181	Optional
5	7	PWSize	Size of pointers for Hardware Page Walker	Section 9.21 on page 184	Optional
6	0	Wired	Controls the number of fixed (“wired”) TLB entries	Section 9.22 on page 191	Required (TLB MMU); Optional (Others)
6	1	SRSCnf0	Per-VPE register indicating and optionally controlling shadow register set configuration	MIPS®MT Module Specification	Required (MIPS MT Module); Optional (Others)
6	2	SRSCnf1	Per-VPE register indicating and optionally controlling shadow register set configuration	MIPS®MT Module Specification	Optional
6	3	SRSCnf2	Per-VPE register indicating and optionally controlling shadow register set configuration	MIPS®MT Module Specification	Optional
6	4	SRSCnf3	Per-VPE register indicating and optionally controlling shadow register set configuration	MIPS®MT Module Specification	Optional
6	5	SRSCnf4	Per-VPE register indicating and optionally controlling shadow register set configuration	MIPS®MT Module Specification	Optional
6	6	PWCtl	HW Page Walker Control	Section 9.23 on page 193	Optional
7	0	HWREna	Enables access via the RDHWR instruction to selected hardware registers	Section 9.24 on page 197	Required (Release 2)
7	1-7		Reserved for future extensions		Reserved
8	0	BadVAddr	Reports the address for the most recent address-related exception	Section 9.25 on page 199	Required

Table 9.1 Coprocessor 0 Registers in Numerical Order (Continued)

Register Number	Sel ¹	Register Name	Function	Reference	Compliance Level
8	1	BadInstr	Reports the instruction which caused the most recent exception.	Section 9.26 on page 201	Optional (Pre-Release 6) Required (Release 6)
8	2	BadInstrP	Reports the branch instruction if a delay slot caused the most recent exception.	Section 9.27 on page 203	Optional (Pre-Release 6) Required (Release 6)
9	0	Count	Processor cycle count	Section 9.28 on page 205	Required
9	6-7		Available for implementation-dependent user	Section 9.29 on page 205	implementation-dependent
10	0	EntryHi	High-order portion of the TLB entry	Section 9.30 on page 207	Required (TLB MMU); Optional (Others)
10	4	GuestCtl1	GuestID of virtualized Guest	MIPS® VZE Module Specification	Required (MIPS VZE Module; Optional (Others))
10	5	GuestCtl2	Guest Interrupt Control	MIPS® VZE Module Specification	Required (MIPS VZE Module; Optional (Others))
10	6	GuestCtl3	Guest Shadow Register Set Control	MIPS® VZE Module Specification	Required (MIPS VZE Module; Optional (Others))
11	0	Compare	Timer interrupt control	Section 9.31 on page 211	Required
11	4	GuestCtl0Ext	Extension of GuestCtl0	MIPS® VZE Module Specification	Required (MIPS VZE Module; Optional (Others))
11	6-7		Available for implementation-dependent user	Section 9.32 on page 211	implementation-dependent
12	0	Status	Processor status and control	Section 9.33 on page 213	Required
12	1	IntCtl	Interrupt system status and control	Section 9.34 on page 225	Required (Release 2)
12	2	SRSCtl	Shadow register set status and control	Section 9.35 on page 229	Required (Release 2)
12	3	SRSTMap	Shadow set IPL mapping	Section 9.36 on page 233	Required (Release 2 and shadow sets implemented)
12	4	View_IPL	Contiguous view of IM and IPL fields.	MIPS® MCU ASE Specification	Required (MIPS MCU ASE); Optional (Others)
12	5	SRSTMap2	Shadow set IPL mapping	MIPS® MCU ASE Specification	Required (MIPS MCU ASE); Optional (Others)

Table 9.1 Coprocessor 0 Registers in Numerical Order (Continued)

Register Number	Sel ¹	Register Name	Function	Reference	Compliance Level
12	6	GuestCtl0	Control of Virtualized Guest OS	MIPS® VZE Module Specification	Required (MIPS VZE Module); Optional (Others)
12	7	GTOffset	Guest Timer Offset	MIPS® VZE Module Specification	Required (MIPS VZE Module); Optional (Others)
13	0	Cause	Cause of last general exception	Section 9.37 on page 235	Required
13	4	View_RIPL	Contiguous view of IP and RIPL fields.	MIPS® MCU ASE Specification	Required (MIPS MCU ASE); Optional (Others)
13	5	NestedExc	Nested exception Support - EXL, ERL values at current exception	Section 9.38 on page 241	Optional
14	0	EPC	Program counter at last exception	Section 9.39 on page 243	Required
14	2	NestedEPC	Nested exception Support - Program Counter at current exception	Section 9.40 on page 245	Optional
15	0	PRId	Processor identification and revision	Section 9.41 on page 247	Required
15	1	EBase	Exception vector base register	Section 9.42 on page 249	Required (Release 2)
15	2	CDMMBase	Common Device Memory Map Base register	Section 9.43 on page 253	Optional
15	3	CMGCRBase	Coherency Manager Global Control Register Base register	Section 9.44 on page 255	Optional
16	0	Config	Configuration register	Section 9.46 on page 259	Required
16	1	Config1	Configuration register 1	Section 9.47 on page 263	Required
16	2	Config2	Configuration register 2	Section 9.48 on page 267	Optional

16	4	Config5	Configuration register 5	Section 9.51 on page 285	Optional
16	6-7		Available for implementation-dependent user	Section 9.52 on page 293	implementation-dependent
17	0	LLAddr	Load linked address	Section 9.53 on page 295	Optional
18	0-n	WatchLo	Watchpoint address	Section 9.56 on page 307	Optional

Table 9.1 Coprocessor 0 Registers in Numerical Order (Continued)

Register Number	Sel ¹	Register Name	Function	Reference	Compliance Level
19	0-n	WatchHi	Watchpoint control	Section 9.57 on page 309	Optional
20	0	XContext	Extended Addressing Page Table Context	Section 9.58 on page 311	Required (64-bit TLB MMU) Optional (Others)
21	all		Reserved for future extensions.		Reserved
22	all		Available for implementation-dependent use	Section 9.59 on page 315	implementation-dependent
23	0	Debug	EJTAG Debug register	EJTAG Specification	Optional
23	1	TraceControl	PDtrace control register	PDtrace Specification	Optional
23	2	TraceControl2	PDtrace control register	PDtrace Specification	Optional
23	3	UserTraceData1	PDtrace control register	PDtrace Specification	Optional
23	4	TraceIBPC	PDtrace control register	PDtrace Specification	Optional
23	5	TraceDBPC	PDtrace control register	PDtrace Specification	Optional
23	6	Debug2	EJTAG Debug2 register	EJTAG Specification	Optional
24	0	DEPC	Program counter at last EJTAG debug exception	EJTAG Specification	Optional
24	2	TraceContol3	PDtrace control register	PDtrace Specification	Optional
24	3	UserTraceData2	PDtrace control register	PDtrace Specification	Optional
25	0-n	PerfCnt	Performance counter interface	Section 9.63 on page 323	Recommended
26	0	ErrCtl	Parity/ECC error control and status	Section 9.64 on page 329	Optional
27	0-3	CacheErr	Cache parity error control and status	Section 9.65 on page 331	Optional
28	even selects	TagLo	Low-order portion of cache tag interface	Section 9.66 on page 333	Required (Cache)
28	odd selects	DataLo	Low-order portion of cache data interface	Section 9.67 on page 335	Optional
29	even selects	TagHi	High-order portion of cache tag interface	Section 9.68 on page 337	Required (Cache)
29	odd selects	DataHi	High-order portion of cache data interface	Section 9.69 on page 339	Optional
30	0	ErrorEPC	Program counter at last error	Section 9.70 on page 341	Required
31	0	DESAVE	EJTAG debug exception save register	EJTAG Specification	Optional
31	2-7	KScratch <i>n</i>	Scratch Registers for Kernel Mode	Section 9.72 on page 345	Pre-Release 6: Optional; KScratch1 at select 2 and KScratch2 at select 3 are recommended. Release 6: Required.

1. Any select (Sel) value not explicitly noted as available for implementation-dependent use is reserved for future use by the Architecture.

9.2 Notation

For each register described below, field descriptions include the read/write properties of the field, and the reset state of the field. For the read/write properties of the field, the following notation is used:

Table 9.2 Read/Write Bit Field Notation

Read/Write Notation	Hardware Interpretation	Software Interpretation
R/W	<p>A field in which all bits are readable and writable by software and, potentially, by hardware. Hardware updates of this field are visible by software read. Software updates of this field are visible by hardware read.</p> <p>If the Reset State of this field is “Undefined”, either software or hardware must initialize the value before the first read will return a predictable value. This should not be confused with the formal definition of UNDEFINED behavior.</p>	
R	<p>A field which is either static or is updated only by hardware.</p> <p>If the Reset State of this field is either “0”, “Preset”, or “Externally Set”, hardware initializes this field to zero or to the appropriate state, respectively, on powerup. The term “Preset” is used to suggest that the processor establishes the appropriate state, whereas the term “Externally Set” is used to suggest that the state is established via an external source (e.g., personality pins or initialization bit stream). These terms are suggestions only, and are not intended to act as a requirement on the implementation.</p> <p>If the Reset State of this field is “Undefined”, hardware updates this field only under those conditions specified in the description of the field.</p>	<p>A field to which the value written by software is ignored by hardware. Software may write any value to this field without affecting hardware behavior. Software reads of this field return the last value updated by hardware.</p> <p>If the Reset State of this field is “Undefined”, software reads of this field result in an UNPREDICTABLE value except after a hardware update done under the conditions specified in the description of the field.</p>
0	<p>A field which hardware does not update, and for which hardware can assume a zero value.</p>	<p>A field to which the value written by software must be zero. Software writes of non-zero values to this field may result in UNDEFINED behavior of the hardware. Software reads of this field return zero as long as all previous software writes are zero.</p> <p>If the Reset State of this field is “Undefined”, software must write this field with zero before it is guaranteed to read as zero.</p>

9.3 Writing CPU Registers

With certain restrictions, software may assume that it can validly write the value read from a coprocessor 0 register back to that register without having unintended side effects. This rule means that software can read a register, modify one field, and write the value back to the register without having to consider the impact of writes to other fields. Processor designers should take this into consideration when using coprocessor 0 register fields that are reserved for implementations and make sure that the use of these bits is consistent with software assumptions.

Coprocessor 0 Registers

The most significant exception to this rule is a situation in which the processor modifies the register between the software read and write, such as might occur if an exception or interrupt occurs between the read and write. Software must guarantee that such an event does not occur.

Release 6 limits the number of cases where software can cause UNDEFINED or UNPREDICTABLE behavior. For example, in Release 6, for writes to a defined COP0 register field that may have reserved encodings, writes of unsupported values cause the write to be ignored by hardware. This means that no field in the COP0 register is modified unless all fields meet the conditions for writing. An exception to this rule is that if a field is reserved, then a write of a non-zero value to the reserved field is ignored but by itself does not cause the entire write to be dropped.

9.4 Index Register (CP0 Register 0, Select 0)

Compliance Level: *Required* for TLB-based MMUs; *Optional* otherwise.

The *Index* register is a 32-bit read/write register which contains the index used to access the TLB for TLBP, TLBR, and TLBWI instructions. The width of the index field is implementation-dependent as a function of the number of TLB entries that are implemented. The minimum value for TLB-based MMUs is $\text{Ceiling}(\text{Log}_2(\text{TLBEntries}))$. For example, six bits are required for a TLB with 48 entries).

For Pre-Release 6: The operation of the processor is **UNDEFINED** if a value greater than or equal to the number of TLB entries is written to the *Index* register.

For Release 6: Hardware leaves the *Index* field unchanged if a value greater than, or equal to, the number of TLB entries is written to the *Index* register.

Figure 9.1 shows the format of the *Index* register; Table 9.3 describes the *Index* register fields.

Figure 9.1 Index Register Format

Table 9.3 Index Register Field Descriptions

Fields		Description	Read/Write	Reset State	Compliance						
Name	Bits										
P	31	<p>Probe Failure. Hardware writes this bit during execution of the TLBP instruction to indicate whether a TLB match occurred. Release 6 requires that this bit be R/W to allow software to set the bit to 1 after a TLBP has cleared the bit. Implementations may use P=0 to cause a TLBWR to write to a TLB entry other than that indexed by the Index field. Hardware ignores a write of 0 to this bit.</p> <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>A match occurred, and the <i>Index</i> field contains the index of the matching entry</td></tr><tr><td>1</td><td>No match occurred and the Index field is UNPREDICTABLE</td></tr></table>	Encoding	Meaning	0	A match occurred, and the <i>Index</i> field contains the index of the matching entry	1	No match occurred and the Index field is UNPREDICTABLE	<p>R (Pre-Release 6)</p> <p>R/W (Release 6)</p>	Undefined	Required
Encoding	Meaning										
0	A match occurred, and the <i>Index</i> field contains the index of the matching entry										
1	No match occurred and the Index field is UNPREDICTABLE										
0	30..n	Must be written as zero; returns zero on read.	0	0	Reserved						

Table 9.3 Index Register Field Descriptions (Continued)

Fields		Description	Read/Write	Reset State	Compliance
Name	Bits				
Index	n-1..0	<p>TLB index. Software writes this field to provide the index to the TLB entry referenced by the TLBR and TLBWI instructions.</p> <p>Hardware writes this field with the index of the matching TLB entry during execution of the TLBP instruction. If the TLBP fails to find a match, the contents of this field are UNPREDICTABLE.</p>	R/W	Undefined	Required

9.5 VPControl (CP0 Register 0, Select 4)

Compliance Level: *Required*. if Release 6 Virtual Processor based Multi-threading supported (i.e., $Config5_{VP}=1$).

CP0 Virtual Processor Control register provides control and configuration support for Release 6 multi-threading.

Figure 9.2 shows the format of the *VPControl* register; Table 9.4 describes the *VPControl* register fields.

Figure 9.2 VPControl Register Format

Table 9.4 VPControl Register Field Descriptions

Fields		Description	Read/ Write	Reset State	Compliance
Name	Bits				
0	31:1	0	0	0	Reserved
DIS	0	For a VP that reads <i>VPControl</i> , all other VPs on the core have been disabled if $VPControl_{DIS}=1$. A DVP instruction executed on this virtual processor has disabled fetch on all other virtual processors in the physical core. An EVP instruction is the only means to subsequently clear DIS. See definition of Release 6 multi-threading DVP and EVP instructions for supporting information.	R	0	Required

9.6 Random Register (CP0 Register 1, Select 0)

Compliance Level: *Required* for TLB-based MMUs; *Optional* otherwise. Pre-Release 6 only; deprecated in Release 6.

The *Random* register is a read-only register whose value is used to index the TLB during a TLBWR instruction. The width of the Random field is calculated in the same manner as that described for the *Index* register above.

The value of the register varies between an upper and lower bound as follow:

- A lower bound is set by the number of TLB entries reserved for exclusive use by the operating system (the contents of the *Wired* register). The entry indexed by the *Wired* register is the first entry available to be written by a TLB Write Random operation.
- An upper bound is set by the total number of TLB entries minus 1.

Within the required constraints of the upper and lower bounds, the manner in which the processor selects values for the *Random* register is implementation-dependent.

The processor initializes the *Random* register to the upper bound on a Reset Exception, and when the *Wired* register is written.

Figure 9.3 shows the format of the *Random* register; Table 9.5 describes the *Random* register fields.

Figure 9.3 Random Register Format

Table 9.5 Random Register Field Descriptions

Fields		Description	Read/ Write	Reset State	Compliance
Name	Bits				
0	31..n	Must be written as zero; returns zero on read.	0	0	Reserved
Random	n-1..0	TLB Random Index	R	TLB Entries - 1	Required

9.7 EntryLo0, EntryLo1 (CP0 Registers 2 and 3, Select 0)

Compliance Level: *EntryLo0* is *Required* for a TLB-based MMU; *Optional* otherwise.

Compliance Level: *EntryLo1* is *Required* for a TLB-based MMU; *Optional* otherwise.

The pair of *EntryLo* registers act as the interface between the TLB and the TLBP, TLBR, TLBWI, and TLBWR instructions. *EntryLo0* holds the entries for even pages and *EntryLo1* holds the entries for odd pages.

Software may determine the value of *PABITS* by writing all ones to the *EntryLo0* or *EntryLo1* registers and reading the value back. Bits read as “1” from the *PFN* field allow software to determine the boundary between the *PFN/PFNX* and *Fill* fields to calculate the value of *PABITS*.

The contents of the *EntryLo0* and *EntryLo1* registers are not defined after an address error exception, and some fields may be modified by hardware during the address-error exception sequence. Software writes to the *EntryHi* register (via MTC0 or DMTC0) do not cause the implicit update of address-related fields in the *BadVAddr* or *Context* registers.

For Release 1 of the Architecture, [Figure 9-4](#) shows the format of the *EntryLo0* and *EntryLo1* registers; [Table 9.6](#) describes the *EntryLo0* and *EntryLo1* register fields.

For Release 2 of the Architecture, [Figure 9-5](#) shows the format of the *EntryLo0* and *EntryLo1* registers; [Table 9.7](#) describes the *EntryLo0* and *EntryLo1* register fields. Release 2 of the architecture added support for physical address spaces beyond 36 bits in range and support for 1 kB pages.

For Release 3 of the Architecture, [Figure 9-6](#) and [Figure 9-7](#) shows the format of the *EntryLo0* and *EntryLo1* registers; [Table 9.8](#) and [Table 9.9](#) describe the *EntryLo0* and *EntryLo1* register fields. Release 3 of the architecture added support for Read-Inhibit and Execute-Inhibit page protection bits. These protection bits appear in different bit locations for the DMFC0/DMTC0 and MFC0/MTC0 instruction pairs to provide compatibility between the 32-bit and 64-bit architectures.

Figure 9-4 EntryLo0, EntryLo1 Register Format in Release 1 of the Architecture

Table 9.6 EntryLo0, EntryLo1 Register Field Descriptions in Release 1 of the Architecture

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
Fill	63..30	These bits are ignored on write and return zero on read. The boundaries of this field change as a function of the value of <i>PABITS</i> . See Table 9.10 for more information.	R	0	Required

Table 9.6 EntryLo0, EntryLo1 Register Field Descriptions in Release 1 of the Architecture

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
PFN	29..6	Page Frame Number. Corresponds to bits <i>PABITS</i> -1..12 of the physical address, where <i>PABITS</i> is the width of the physical address in bits. The boundaries of this field change as a function of the value of <i>PABITS</i> . See Table 9.10 for more information.	R/W	Undefined	Required
C	5..3	Cacheability and Coherency Attribute of the page. See Table 9.11 below.	R/W	Undefined	Required
D	2	“Dirty” bit, indicating that the page is writable. If this bit is a one, stores to the page are permitted. If this bit is a zero, stores to the page cause a TLB Modified exception. Kernel software may use this bit to implement paging algorithms that require knowing which pages have been written. If this bit is always zero when a page is initially mapped, the TLB Modified exception that results on any store to the page can be used to update kernel data structures that indicate that the page was actually written.	R/W	Undefined	Required
V	1	Valid bit, indicating that the TLB entry, and thus the virtual page mapping are valid. If this bit is a one, accesses to the page are permitted. If this bit is a zero, accesses to the page cause a TLB Invalid exception.	R/W	Undefined	Required
G	0	Global bit. On a TLB write, the logical AND of the G bits from both <i>EntryLo0</i> and <i>EntryLo1</i> becomes the G bit in the TLB entry. If the TLB entry G bit is a one, ASID comparisons are ignored during TLB matches. On a read from a TLB entry, the G bits of both <i>EntryLo0</i> and <i>EntryLo1</i> reflect the state of the TLB G bit.	R/W	Undefined	Required (TLB MMU)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
PFN	29..6	<p>Page Frame Number. This field contains least-significant bits of the physical page number corresponding to the virtual page. If the processor is enabled to support large physical addresses, the <i>PFNX</i> field described above is concatenated with the <i>PFN</i> field to form the full page frame number. If the processor is not enabled to support large physical addresses, the entire page frame number is represented by this field. See the description of the <i>PFNX</i> field above for more information.</p> <p>If the processor is enabled to support 1 kB pages (<i>Config3_{SP}</i> = 1 and <i>PageGrain_{ESP}</i> = 1), the <i>PFN</i> field corresponds to bits 33..10 of the physical address (the field is shifted left by 2 bits relative to the Release 1 definition to make room for PA_{11..10}).</p> <p>If the processor is not enabled to support 1 kB pages (<i>Config3_{SP}</i> = 0 or <i>PageGrain_{ESP}</i> = 0), the <i>PFN</i> field corresponds to bits 35..12 of the physical address. The boundaries of this field change as a function of the value of <i>PABITS</i>. See Table 9.10 for more information.</p>	R/W	Undefined	Required
C	5..3	The definition of this field is unchanged from Release 1. See Table 9.6 above and Table 9.11 below.	R/W	Undefined	Required
D	2	The definition of this field is unchanged from Release 1. See Table 9.6 above.	R/W	Undefined	Required
V	1	The definition of this field is unchanged from Release 1. See Table 9.6 above.	R/W	Undefined	Required
G	0	The definition of this field is unchanged from Release 1. See Table 9.6 above.	R/W	Undefined	Required (TLB MMU)

For the MTC0 and MFC0 instructions in a MIPS64 Release 3 implementation, the *RI* and *XI* bits are visible at their MIPS32 locations. This allows for backward compatibility with MIPS32 when using the *RI/XI* protection bits.

MTC0 on a MIPS64 Release 3 machine will cause all zeros to be written to the *PFNX* field (this field is not visible by software via the MTC0/MFC0 instructions).

Figure 9-7 EntryLo0, EntryLo1 Register Format in Release 3 of the Architecture when Accessed using MFC0 and MTC0 Instructions

Table 9.9 EntryLo0, EntryLo1 Register Field Descriptions in Release 3 of the Architecture when Accessed using MFC0 and MTC0 Instructions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
SignExt	63..32	The GPR bits are ignored on write. The <i>PFNX</i> field is written with zeros. On a read, the GPR bits are signed extended from the <i>RI</i> bit.	R	0	Required.
RI	31	Read Inhibit. If this bit is set in a TLB entry, an attempt, other than a MIPS16 PC-relative load , to read data on the virtual page causes a TLB Invalid or a TLBRI exception, even if the <i>V</i> (Valid) bit is set. The <i>RI</i> bit is writable only if the <i>RIE</i> bit of the <i>PageGrain</i> register is set. If the <i>RIE</i> bit of <i>PageGrain</i> is not set, the <i>RI</i> bit of <i>EntryLo0/EntryLo1</i> is set to zero on any write to the register, regardless of the value written. This bit is optional and its existence is denoted by the <i>Config3_{RXI}</i> or <i>Config3_{SM}</i> register fields.	R/W	0	Required by SmartMIPS ASE; Optional otherwise If not implemented, this bit location is part of the <i>Fill</i> field.
XI	30	Execute Inhibit. If this bit is set in a TLB entry, an attempt to fetch an instruction or to load MIPS16 PC-relative data from the virtual page causes a TLB Invalid or a TLBXI exception, even if the <i>V</i> (Valid) bit is set. The <i>XI</i> bit is writable only if the <i>XIE</i> bit of the <i>PageGrain</i> register is set. If the <i>XIE</i> bit of <i>PageGrain</i> is not set, the <i>XI</i> bit of <i>EntryLo0/EntryLo1</i> is set to zero on any write to the register, regardless of the value written. This bit is optional and its existence is denoted by the <i>Config3_{RXI}</i> or <i>Config3_{SM}</i> register fields.	R/W	0	Required by SmartMIPS ASE; Optional otherwise If not implemented, this bit location is part of the <i>Fill</i> field.
PFN	29..6	Page Frame Number. This field contains least-significant bits of the physical page number corresponding to the virtual page. If the processor is enabled to support large physical addresses, the <i>PFNX</i> field, described above is concatenated with the <i>PFN</i> field to form the full page frame number. If the processor is not enabled to support large physical addresses, the entire page frame number is represented by this field. See the description of the <i>PFNX</i> field above for more information. If the processor is enabled to support 1 kB pages (<i>Config3_{SP}</i> = 1 and <i>PageGrain_{ESP}</i> = 1), the <i>PFN</i> field corresponds to bits 33..10 of the physical address (the field is shifted left by 2 bits relative to the Release 1 definition to make room for <i>PA_{11..10}</i>). If the processor is not enabled to support 1 kB pages (<i>Config3_{SP}</i> = 0 or <i>PageGrain_{ESP}</i> = 0), the <i>PFN</i> field corresponds to bits 35..12 of the physical address. The boundaries of this field change as a function of the value of <i>PABITS</i> . See Table 9.10 for more information.	R/W	Undefined	Required

Table 9.9 EntryLo0, EntryLo1 Register Field Descriptions in Release 3 of the Architecture when Accessed using MFC0 and MTC0 Instructions (Continued)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
C	5..3	The definition of this field is unchanged from Release 1. See Table 9.6 above and Table 9.11 below.	R/W	Undefined	Required
D	2	The definition of this field is unchanged from Release 1. See Table 9.6 above.	R/W	Undefined	Required
V	1	The definition of this field is unchanged from Release 1. See Table 9.6 above.	R/W	Undefined	Required
G	0	The definition of this field is unchanged from Release 1. See Table 9.6 above.	R/W	Undefined	Required (TLB MMU)

[Table 9.10](#) shows the movement of the *Fill*, *PFNX*, and *PFN* fields as a function of 1 kB page support enabled, and the value of *PABITS*. Note that in implementations of the Architecture, *PABITS* can never be larger than 36 bits and there is no support for 1 kB pages, so only the second row of the table applies in Release 1.

Table 9.10 EntryLo Field Widths as a Function of PABITS

1 kB Page Support Enabled?	PABITS Value	Corresponding EntryLo Field Bit Ranges			Required Release
		Fill Field	PFNX Field	PFN Field	
No	$59 \geq PABITS > 36$	63..(53-(59-PABITS)) Example: 63..53 if PABITS = 59 63..31 if PABITS = 37	(52-(59-PABITS))..30E Example: 52..30 if PABITS = 59 30..30 if PABITS = 37 EntryLo _{52..30} = PA _{59..36}	29..6 EntryLo _{29..6} = PA _{35..12}	Release 5
	$36 \geq PABITS > 12$	63..(30-(36-PABITS)) Example: 63..30 if PABITS = 36 63..7 if PABITS = 13	Displaced by the Fill Field	(29-(36-PABITS))..6 Example: 29..6 if PABITS = 36 6..6 if PABITS = 13 EntryLo _{29..6} = PA _{35..12}	Release 1
Yes	$59 \geq PABITS > 34$	63..(55-(59-PABITS)) Example: 63..55 if PABITS = 59 63..31 if PABITS = 35	(54-(59-PABITS))..30 Example: 54..30 if PABITS = 59 31..30 if PABITS = 35 EntryLo _{54..30} = PA _{59..34}	29..6 EntryLo _{29..6} = PA _{33..10}	Release 5
	$34 \geq PABITS > 10$	63..(30-(34-PABITS)) Example: 63..30 if PABITS = 34 63..7 if PABITS = 11	Displaced by the Fill Field	(29-(34-PABITS))..6 Example: 29..6 if PABITS = 34 6..6 if PABITS = 11 EntryLo _{29..6} = PA _{33..10}	Release 2

Programming Note:

In implementations of Release 2 of the Architecture (and any release prior to Release 6), the *PFNX* and *PFN* fields of both the *EntryLo0* and *EntryLo1* registers must be written with zero, and the TLB must be flushed before each instance in which the value of the *PageGrain* register is changed. This operation must be carried out while running in an unmapped address space. The operation of the processor is **UNDEFINED** if this sequence is not done.

For Release 6, this is not a requirement because support for *EntryHi_{EHINV}* is mandatory. Instead, software must invalidate the TLB entries explicitly using TLBWI with *EntryHi_{EHINV}*=1.

Table 9.11 lists the encoding of the *C* field of the *EntryLo0* and *EntryLo1* registers and the *K0* field of the *Config* register. An implementation may choose to implement a subset of the cache coherency attributes shown, but must implement at least encodings 2 and 3 such that software can always depend on these encodings working appropriately.

In other cases of Pre-Release 6 implementations, the operation of the processor is **UNDEFINED** if software uses a TLB mapping (either for an instruction fetch or for a load/store instruction) that was created with a *C* field encoding which is RESERVED for the implementation. In Release 6, hardware must ignore writes of unsupported values of the *C* field for the implementation.

Table 9.11 lists the required and optional encodings for the cacheability and coherency attributes.

Table 9.11 Cacheability and Coherency Attributes

C(5:3) Value	Cacheability and Coherency Attributes With Historical Usage	Compliance
0	• Available for implementation-dependent use	Optional
1	• Available for implementation-dependent use	Optional
2	• Uncached	Required
3	• Cacheable	Required
4	• Available for implementation-dependent use	Optional
5	• Available for implementation-dependent use	Optional
6	• Available for implementation-dependent use	Optional
7	• Available for implementation-dependent use	Optional

9.8 Global Number Register (COP0 Register 3, Select 1)

Compliance Level: *Optional Release 6*

The *Global Number* register is required if a Release 6 core implements multi-threading.

The unique name of a virtual processor (VPNum; see COP0 EBASE) in a cluster can be derived from the contents of this register by one of the two methods described below. The method must be uniformly applied to all virtual processors in the system.

- $VPNum = CoreNum + VPId$. This method allows for contiguous numbering of virtual processors in a cluster with heterogenous multi-threading (cores with different thread counts).
- $VPNum = CoreNum \times Max\text{-}VP + VPId$, where Max-VP is the maximum virtual processor count in any core in a cluster. This results in non-contiguous numbering of virtual processors in a cluster.

See [Table 9.13](#) for examples.

The naming convention is hierarchical. The unique name of a virtual processor in the system is ClusterNum.VPNum.

The fields where indicated can be externally programmable. This allows for reallocation of software threads from virtual processor to virtual processor by reassigning the VPNum to the virtual processor.

ClusterNum is optional and only required in a system that supports clusters of cores.

[Figure 9.8](#) shows the format of the *Global Number* register; [Table 9.12](#) describes the *Global Number* register fields.

Figure 9.8 Global Number Register Format

Table 9.12 Global Number Register Field Descriptions

Fields		Description	Read/Write	Reset State	Compliance
Name	Bits				
0	31:20	Reserved.	0	0	Reserved
ClusterNum	19:16	A unique number assigned to a cluster of cores in the system. Reserved if clustering is not implemented. Unimplemented bits in the field are not writeable; reads return 0. This field is read-only, but can be preset, or optionally can be programmed by a register external to COP0 through a memory mapped register.	R	Preset by hardware or externally set	Optional
0	15:12	Reserved.	0	0	Reserved

Table 9.12 Global Number Register Field Descriptions (Continued)

Fields		Description	Read/Write	Reset State	Compliance
Name	Bits				
CoreNum	11:8	A unique number assigned to a physical core in a cluster. Unimplemented bits in the field are not writeable; reads return 0. This field is read-only, but can be preset, or optionally can be programmed by a register external to COP0 through a memory mapped register.	R	Preset by hardware or externally set	Required
VPId	7:0	A unique number assigned to a virtual processor in a core. Unimplemented bits in the field are not writeable; reads return 0. The number of unimplemented bits is dependent on whether contiguous or non-contiguous numbering is supported. If contiguous, then VPId size equals $\text{ceiling}(\log_2(\text{total VP count in cluster}))$. If non-contiguous, then VPId size equals $\log_2(\text{maximum VP count of any core})$. This field is read-only, but can be preset, or optionally can be programmed by a register external to COP0 through a memory mapped register.	R	Preset by hardware or externally set	Required

Table 9.13 Deriving Unique VPNum

CoreNum	# of VPs	Contiguous Numbering		Non-Contiguous Numbering	
		VPId	VPNum	VPId	VPNum
0	4	0, 1, 2, 3	0, 1, 2, 3	0, 1, 2, 3	0, 1, 2, 3
1	2	3, 4	4, 5	0, 1	4, 5
2	1	4	6	0	8
3	4	4, 5, 6, 7	7, 8, 9, 10	0, 1, 2, 3	12, 13, 14, 15

9.9 Context Register (CP0 Register 4, Select 0)

Compliance Level: *Required* for TLB-based MMUs; *Optional* otherwise.

The *Context* register is a read/write register containing a pointer to an entry in the page table entry (PTE) array. This array is an operating system data structure that stores virtual-to-physical translations. During a TLB miss, the operating system loads the TLB with the missing translation from the PTE array. The *Context* register is primarily intended for use with the TLB Refill handler, but is also loaded by hardware on an XTLB Refill and may be used by software in that handler. The *Context* register duplicates some of the information provided in the *BadVAddr* register.

If $Config3_{CTXTC}=0$ and $Config3_{SM}=0$ then the *Context* register is organized in such a way that the operating system can directly reference a 16-byte structure in memory that describes the mapping. For PTE structures of other sizes, the content of this register can be used by the TLB refill handler after appropriate shifting and masking.

If $Config3_{CTXTC}=0$ and $Config3_{SM}=0$ then a TLB exception (TLB Refill, XTLB Refill, TLB Invalid, or TLB Modified) causes bits $VA_{31..13}$ of the virtual address to be written into the *BadVPN2* field of the *Context* register. The *PTEBase* field is written and used by the operating system.

The *BadVPN2* field of the *Context* register is not defined after an address error exception and this field may be modified by hardware during the address error exception sequence.

Figure 9.9 shows the format of the *Context* Register when $Config3_{CTXTC}=0$ and $Config3_{SM}=0$; Table 9.14 describes the *Context* register fields $Config3_{CTXTC}=0$ and $Config3_{SM}=0$.

Figure 9.9 Context Register Format when $Config3_{CTXTC}=0$ and $Config3_{SM}=0$

63	23 22	4 3	0
PTEBase	BadVPN2	0	

Table 9.14 Context Register Field Descriptions when $Config3_{CTXTC}=0$ and $Config3_{SM}=0$

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
PTEBase	63..23	This field is for use by the operating system and is normally written with a value that allows the operating system to use the <i>Context</i> Register as a pointer into the current PTE array in memory.	R/W	Undefined	Required
BadVPN2	22..4	This field is written by hardware on a TLB exception. It contains bits $VA_{31..13}$ of the virtual address that caused the exception.	R	Undefined	Required
0	3..0	Must be written as zero; returns zero on read.	0	0	Reserved

If $Config3_{CTXTC}=1$ or $Config3_{SM}=1$ then the pointer implemented by the *Context* register can point to any power-of-two-sized PTE structure within memory. This allows the TLB refill handler to use the pointer without additional

shifting and masking steps. Depending on the value in the *ContextConfig* register, it may point to an 8-byte pair of 32-bit PTEs within a single-level page table scheme, or to a first level page directory entry in a two-level lookup scheme.

If *Config3_{CTXTC}* = 1 or *Config3_{SM}* = 1 then the a TLB exception (Refill, Invalid, or Modified) causes bits $VA_{31:31-((X-Y)-1)}$ to be written to a variable range of bits “(X-1):Y” of the *Context* register, where this range corresponds to the contiguous range of set bits in the *ContextConfig* register. Bits 63:X are R/W to software, and are unaffected by the exception. Bits Y-1:0 are unaffected by the exception. If X = 23 and Y = 4, i.e. bits 22:4 are set in *ContextConfig*, the behavior is identical to the standard MIPS64 *Context* register (bits 22:4 are filled with $VA_{31:13}$). Although the fields have been made variable in size and interpretation, the MIPS64 nomenclature is retained. Bits 63:X are referred to as the *PTEBase* field, and bits X-1:Y are referred to as *BadVPN2*.

If *Config3_{SM}* = 1 then Bits Y-1:0 will always read as 0.

The value of the *Context* register is **UNPREDICTABLE** following a modification of the contents of the *ContextConfig* register.

Figure 9.10 shows the format of the *Context* Register when *Config3_{CTXTC}* = 1 or *Config3_{SM}* = 1; Table 9.15 describes the *Context* register fields *Config3_{CTXTC}* = 1 or *Config3_{SM}* = 1.

Figure 9.10 Context Register Format when *Config3_{CTXTC}* = 1 or *Config3_{SM}* = 1

63	X X-1	Y Y-1	0

Table 9.15 Context Register Field Descriptions when *Config3_{CTXTC}* = 1 or *Config3_{SM}* = 1

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
PTEBase	Variable, 63:X where X in {31..0}. May be null.	This field is for use by the operating system and is normally written with a value that allows the operating system to use the <i>Context</i> Register as a pointer to an array of data structures in memory corresponding to the address region containing the virtual address which caused the exception.	R/W	Undefined	Required
BadVPN2	Variable, (X-1):Y where X in {32..1} and Y in {31..0}. May be null.	This field is written by hardware on a TLB exception. It contains bits $VA_{31:31-((X-Y)-1)}$ of the virtual address that caused the exception.	R	Undefined	Required

Table 9.15 Context Register Field Descriptions when Config3_{CTXT}=1 or Config3_{SM}=1 (Continued)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
0	Variable, (Y-1):0 where Y in {31:1}. May be null.	Must be written as zero; returns zero on read.	R or R/W (R/W only allowed for Config3 _{CTXT} =1)	0 (if R) or Undefined (if R/W)	Reserved

9.10 ContextConfig Register (CP0 Register 4, Select 1)

Compliance Level: *Optional.*

The *ContextConfig* register defines the bits of the *Context* register into which the bits starting from 31 of the virtual address causing a TLB exception will be written, and how many bits of that virtual address will be extracted. Bits above the selected field of the *Context* register are R/W to software and serve as the *PTEBase* field. Bits below the selected field of the *Context* register will be unaffected by TLB exceptions.

The field to contain the virtual address index is defined by a single block of contiguous non-zero bits within the *ContextConfig* register's *VirtualIndex* field. Any zero bits to the right of the least-significant one bit cause the corresponding *Context* register bits to be unaffected by TLB exceptions. Any zero bits to the left of the most-significant one bit cause the corresponding *Context* register bits to be R/W to software and unaffected by TLB exceptions.

If *Config3_{SM}* is set, then any zero bits to the right of the least significant one bit causes the corresponding *Context* register bits to be read as zero.

It is permissible to implement a subset of the *ContextConfig* register, in which some number of bits are read-only and set to one or zero as appropriate. Software can determine whether a specific setting is implemented by writing that value into the register and reading back the register value. If the read value matches the original written value exactly, then the setting is supported. It is implementation specific what value is read back when the setting is not implemented except that the read value does not match the original written value. All implementations of the *ContextConfig* register must allow for the emulation of the MIPS64/microMIPS64 fixed *Context* register configuration.

This paragraph describes restrictions on how the *ContextConfig* register may be programmed. The set bits of *ContextConfig* define the *BadVPN2* field within the *Config* register. The *BadVPN2* field cannot contain address bits which are used to index a memory location within the even-odd page pairs used by the JTLB entries. This limits the least significant writable bit within *ContextConfig* to the bits that represents *BadVPN2* of the smallest implemented page size. For example, if the smallest implemented page size is 4 kB, virtual address bit 13 is the least significant bit of the *BadVPN2* field. Another example: if 1 kB was the smallest implemented page size then the least significant writable bit within *ContextConfig* would correspond to virtual address bit 11.

A value of all zeroes means that the full 64 bits of the *Context* register are R/W for software and unaffected by TLB exceptions.

The *ContextConfig* register is optional and its existence is denoted by the *Config3_{CTXTC}* or *Config3_{SM}* register fields.

Figure 9.11 shows the formats of the *ContextConfig* Register; Table 9.16 describes the *ContextConfig* register fields.

0x007ffff8	Single Level	2K	32 bits/page	RECOMMENDED

9.11 UserLocal Register (CP0 Register 4, Select 2)

Compliance Level: Pre-Release 6: *Recommended*.

Release 6: *Required*

The *UserLocal* register is a read-write register that is not interpreted by the hardware and conditionally readable via the RDHWR instruction.

If the MIPS® MT Module is implemented, the *UserLocal* register is instantiated per TC.

Prior to Release 6, this register only exists if the *Config3_{ULRI}* register field is set.

For Release 6, this register is mandatory, and *Config3_{ULRI}* must be 1.

Figure 9.12 shows the format of the *UserLocal* register; Table 9.18 describes the *UserLocal* register fields.

Figure 9.12 UserLocal Register Format

Table 9.18 UserLocal Register Field Descriptions

Fields		Description	Read/ Write	Reset State	Compliance
Name	Bits				
UserInfor- mation	63..0	This field contains software information that is not interpreted by the hardware.	R/W	Undefined	Required

Programming Notes

Privileged software may write this register with arbitrary information and make it accessible to unprivileged software via register 29 (ULR) of the RDHWR instruction. To do so, bit 29 of the *HWREna* register must be set to a 1 to enable unprivileged access to the register. In some operating environments, the *UserLocal* register contains a pointer to a thread-specific storage block that is obtained via the RDHWR register.

9.12 Debug ContextID (CP0 Register 4, Select 4)

Compliance Level: *Reserved* Pre-Release 6; *Optional* Release 6.

Debug ContextID is programmed by the kernel to provide a process specific tag to be incorporated into MIPS specific hardware debug related mechanisms, examples being trace, PC-sample and breakpoint. The value programmed would typically be unique to a process and as such saved/restored on a process context switch, but may be any supplemental information that can assist debug.

Other than being factored into debug hardware, writes to this register do not have any side-effects on processor operation. Nor is this register to be used to observe side-effects of processor operation.

This register is also not defined as part of the EJTAG Specification i.e., it is not part of the set of *DRSEG* registers accessible when $Debug_{DM}=1$. It is accessible in kernel-mode when $Debug_{DM}=0$.

This register may be present only if $Config1_{EP}=1$. However, it is not a requirement the register be present if $Config1_{EP}=1$.

Figure 9.13 shows the format of the *Debug ContextID* register; Table 9.19 describes the *Debug ContextID* register fields.

Figure 9.13 Debug ContextID Register Format

Table 9.19 Debug ContextID Register Field Descriptions

Fields		Description	Read/ Write	Reset State	Compliance
Name	Bits				
ID	31:0	Provides a process specific tag specifically for use in hardware debug mechanisms. May be used by kernel software to inject any supplemental information for debug purposes.	R/W	Undefined	Required

9.13 XContextConfig Register (CP0 Register 4, Select 3)

Compliance Level: *Optional.*

The *XContextConfig* register defines the bits of the *XContext* register into which the high order bits (starting at SEGBITS-1) of the virtual address causing a TLB exception will be written, and how many bits of that virtual address will be extracted. Bits above the selected field of the *XContext* register serve as the *PTEBase* and R fields. The *PTEBase* field is R/W to software while the R field is written by hardware. Bits below the selected field of the *Context* register will be unaffected by TLB exceptions.

The field to contain the virtual address index is defined by a single block of contiguous non-zero bits within the *XContextConfig* register's *VirtualIndex* field. Any zero bits to the right of the least significant one bit cause the corresponding *XContext* register bits to be unaffected by hardware. Any zero bits to the left of the most significant one bit designate the location of the R field and cause the remaining *XContext* register bits to be R/W to software and unaffected by TLB exceptions.

It is permissible to implement a subset of the *XContextConfig* register, in which some number of bits are read-only and set to one or zero as appropriate. Software can determine whether a specific setting is implemented by writing that value into the register and reading back the register value. If the read value matches the original written value exactly, then the setting is supported. It is implementation specific what value is read back when the setting is not implemented except that the read value does not match the original written value. All implementations of the *XContextConfig* register must allow for the emulation of the MIPS64/microMIPS64 fixed *XContext* register configuration.

This paragraph describes restrictions on how the *XContextConfig* register may be programmed. The set bits of *XContextConfig* define the BadVPN2 field within the *XConfig* register. The BadVPN2 field cannot contain address bits which are used to index a memory location within the even-odd page pairs used by the JTLB entries. This limits the least significant writeable bit within *XContextConfig* to the bits that represents BadVPN2 of the smallest implemented page size. For example, if the smallest implemented page size is 4KB, virtual address bit 13 is the least significant bit of the BadVPN2 field. Another example: if 1KB was the smallest implemented page size then the least significant writeable bit within *XContextConfig* would be the bit corresponding to virtual address bit 11.

In the MIPS64 and microMIPS64 architectures, implementations are allowed to implement virtual address segments which are less than the full 64-bits and have regions in the memory map which are not accessible (accesses to such regions would cause Address Error exceptions). The symbol SEGBITS is used within this document to denote the size of the accessible address segments. The *XConfig* register is meant to be a pointer to a page table data-structure. That page table must reside in memory which is accessible. For that reason, the most significant address bit within the BadVPN2 field can not be larger than the value of SEGBITS-1. This restricts the most significant writeable bit within *XContextConfig* to the bit location that corresponds to VA_{SEGBITS-1} or smaller.

A value of all zeroes means that the full 64 bits of the *XContext* register are R/W for software and unaffected by TLB exceptions.

The *XContextConfig* register is optional and its existence is denoted by the *Config3*_{CTXT} or *Config3*_{SM} register fields.

The PTEBase fields of *Context* and *XContext* register can be of different width and hold different address pointer values. For this reason, the *XContextConfig* and *ContextConfig* registers must be implemented separately, not sharing any storage.

Figure 9.14 shows the formats of the *XContextConfig* Register; Table 9.20 describes the *XContextConfig* register fields.

Figure 9.14 XContextConfig Register Format

63

0

Table 9.20 XContextConfig Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
VirtualIndex	63:0	A mask of 0 to 64 contiguous 1 bits in this field causes the corresponding bits of the <i>XContext</i> register to be written with the high-order bits starting at SEGBITS-1 of the virtual address causing a TLB exception. Behavior of the processor is UNDEFINED if non-contiguous 1 bits are written into the register field.	R/W	bits SEGBITS-13+3:4 are set (these are the bits corresponding to VA _{SEGBITS} -1:13)	Required

9.14 PageMask Register (CP0 Register 5, Select 0)

Compliance Level: *Required* for TLB-based MMUs; *Optional* otherwise.

The *PageMask* register is a read/write register used for reading from and writing to the TLB. It holds a comparison mask that sets the variable page size for each TLB entry, as shown in Table 9.22. Figure 9.15 shows the format of the *PageMask* register; Table 9.21 describes the *PageMask* register fields.

Release 6 removes support for 1 kB pages. Release 6 also introduces optional support for small page sizes, whereas prior to Release 6, all page sizes from 4 kB on must be supported up to the maximum page size for the implementation; however, the range of supported pages must be continuous.

Figure 9.15 PageMask Register Format if Config_{BPG}=0

Figure 9.16 PageMask Register Format if Config_{BPG}=1

Table 9.21 PageMask Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
Mask	if Config _{BPG} =0 28..13 if Config _{BPG} =1 59..13	The Mask field is a bit mask in which a “1” bit indicates that the corresponding bit of the virtual address should not participate in the TLB match. Release 6 makes optional the support for small page sizes from 4 kB onwards. Corresponding bits for pages disabled in the implementation must be read-only 1. For example, if 4 kB pages are disallowed, <i>PageMask</i> [14:13] is read-only 1s. Software can determine the range of supported pages by writing all 1s to determine the most-significant bits that are read-only 0, and writing all 0s to determine least-significant bits that are read-only 1s within <i>PageMask</i> _{Mask} .	R/W	Undefined	Required

Table 9.21 PageMask Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
MaskX	12..11	<p>In Release 2 of the Architecture (and subsequent releases), the MaskX field is an extension to the Mask field to support 1 kB pages with definition and action analogous to that of the Mask field, defined above.</p> <p>If 1 kB pages are enabled ($Config3_{SP} = 1$ and $PageGrain_{ESP} = 1$), these bits are writable and readable, and their values are copied to and from the TLB entry on a TLB write or read, respectively.</p> <p>If 1 kB pages are not enabled ($Config3_{SP} = 0$ or $PageGrain_{ESP} = 0$), these bits are not writable, return zero on read, and the effect on the TLB entry on a write is as if they were written with the value 0b11.</p> <p>In Release 1 of the Architecture, these bits must be written as zero, return zero on read, and have no effect on the virtual address translation.</p> <p>Release 6 disallows 1 kB pages. This field is read-only 0 from Release 6 onwards.</p>	<p>R/W</p> <p>R</p>	<p>0 (See Description)</p> <p>0</p>	<p>Required (Release 2)</p> <p>Reserved (Release 6)</p>

16 kB	0x3	0x3
64 kB	0xF	0x3
256 kB	0x3F	0x3
1 MB	0xFF	0x3

Table 9.22 Values for the Mask and MaskX¹ Fields of the PageMask Register (Continued)

Page Size	Values for Mask field (lsb of value is located at PageMask ₁₃)	Values for MaskX ¹ field
4 MB	0x3FF	0x3
16 MB	0xFFF	0x3
64 MB	0x3FFF	0x3
256 MB	0xFFFF	0x3
1 GB ²	0x3FFFF	0x3
4 GB ²	0xFFFFF	0x3
16 GB ²	0x3FFFFF	0x3
64GB ²	0xFFFFF	0x3
256 GB ²	0x3FFFFFF	0x3
1 TB ²	0xFFFFFFFF	0x3
4 TB ²	0x3FFFFFFF	0x3
16 TB ²	0xFFFFFFFF	0x3
64 TB ²	0x3FFFFFFF	0x3
256 TB ²	0xFFFFFFFF	0x3

1. PageMask_{12..11} = PageMask_{MaskX} exists only on implementations of Release 2 of the architecture and are treated as if they had the value 0b11 if 1K pages are not enabled (*Config3_{SP}* = 0 or *PageGrain_{ESP}* = 0). In Release 6, these bits are reserved.
2. This page size is available only if Config3_{BPG}=1. The left-most bits of the Mask field necessary to represent this page size exist only if Config3_{BPG}=1

It is implementation-dependent how many of the encodings described in Table 9.22 are implemented. All processors must implement the 4 kB page size (prior to Release 6). If a particular page size encoding is not implemented by a processor, a read of the *PageMask* register must return zeros in all bits that correspond to encodings that are not implemented, thereby potentially returning a value different than that written by software. Release 6 requires that unsupported pages from 4 kB onwards have their corresponding bits read-only 1s up to the minimum supported page size.

Software may determine which page sizes are supported by writing all ones to the *PageMask* register, then reading the value back. If a pair of bits reads back as ones, the processor implements that page size.

For Pre-Release 6: The operation of the processor is **UNDEFINED** if software writes the *Mask* field with a value other than one of those listed in Table 9.22, even if the hardware returns a different value on read. Hardware may depend on this requirement in implementing hardware structures

For Release 6: Hardware ignores writes of illegal or unsupported values to the *Mask* field as defined in Table 9.22. A write of all 1s remains consistent with Pre-Release 6 behavior.

Config3_{SP} Programming Note:

In implementations of Release 2 (and subsequent releases prior to Release 6) of the Architecture, the *MaskX* field of the *PageMask* register must be written with 0b11 and the TLB must be flushed before each instance in which the value of the *PageGrain* register is changed. This operation must be carried out while running in an unmapped address space. The operation of the processor is **UNDEFINED** if this sequence is not done.

For Release 6, this is not a requirement because support for *EntryHi_{EHINV}* is mandatory. Instead, software must invalidate the TLB entries explicitly using TLBWI with *EntryHi_{EHINV}*=1.

9.15 PageGrain Register (CP0 Register 5, Select 1)

Compliance Level: *Required* for implementations of Release 2 (and subsequent releases) of the Architecture that include TLB-based MMUs and support 1 kB pages, the XI/RI TLB protection bits, multiple types of Machine Check exceptions, or large physical addresses; *Required* for SmartMIPS™ ASE; *Required* for XPA (*Config3_{LPA}*=1); *Optional* otherwise.

The *PageGrain* register is a read/write register used for enabling 1 kB page support, the XI/RI TLB protection bits, reporting the type of Machine Check exception, and Extended Physical Addressing, and for large physical address support. The *PageGrain* register is present in both the SmartMIPS™ ASE and in Release 2 (and subsequent releases) of the Architecture. As such, the description below only describes the fields relevant to Release 2 of the Architecture. In implementations of both Release 2 of the Architecture and the SmartMIPS™ ASE, the ASE definitions take precedence. Figure 9-17 shows the format of the *PageGrain* register; Table 9.23 describes the *PageGrain* register fields.

Programming Note:

In implementations of Release 2 (and any release prior to Release 6) of the Architecture, the following fields must be written with the specified values, and the TLB must be flushed before each instance in which the value of the *PageGrain* register is changed. This operation must be carried out while running in an unmapped address space. The operation of the processor is **UNDEFINED** if this sequence is not done.

For Release 6: This is not a requirement because support for *EntryHi_{EHINV}* is mandatory. Instead, software must invalidate the TLB entries explicitly using TLBWI and the properties of *EntryHi_{EHINV}*.

Field	Required Value
EntryLo0 _{PFN} , EntryLo1 _{PFN}	0
EntryLo0 _{PFNX} , EntryLo1 _{PFNX}	0

9.15 PageGrain Register (CP0 Register 5, Select 1)

Field	Required Value
PageMask _{MaskX}	0b11
EntryHi _{VPN2X}	0

Note also that if *PageGrain* is changed, a hazard may be created between the instruction that writes *PageGrain* and a subsequent CACHE instruction. This hazard must be cleared using the EHB instruction.

9.16 SegCtl0 (CP0 Register 5, Select 2)

9.17 SegCtl1 (CP0 Register 5, Select 3)

9.18 SegCtl2 (CP0 Register 5, Select 4)

Compliance Level: *Required* for programmable memory segmentation; *Optional* otherwise.

The *Segmentation Control* registers allow configuring the memory segmentation system. If implemented, the Segmentation Configurations are always active.

The 32-bit Compatibility Address Space is split into six segments. The behavior of each region is controlled by a Segment Configuration. See [Section 4.13 “Segmentation Control”](#).

The highest and lowest 2GB of the address space correspond to the 32-bit Compatibility Address Space.

Segmentation Control allows address-specific behaviors defined by the Privileged Resource Architecture to be modified or disabled.

The *Segmentation Control* registers are instantiated per-VPE in an MT Module processor.

The existence of the *Segmentation Control* registers is denoted by the SC field within the *Config3* register.

The *EntryHi* EHINV TLB invalidate feature is required by Segmentation Control. The legacy software method of representing an invalid TLB entry by using an unmapped address value is not guaranteed to work.

For MIPS64 segments, the KX, SX and UX bits in *Status* are used together with the access control mode from the Segment Configuration. The access control mode is set with the *CFG_{AM}* field.

Each Access Mode allowed by the Segment Configuration has an associated minimum privilege level ([Table 9.29](#)), KERNEL (AM = UK, MK or XKP), SUPERVISOR (AM = MSK) or USER (AM = MUSK, MUSUK or UUSK).

Access to segments with a minimum privilege level of KERNEL are allowed when the processor is operating with KERNEL privilege and the *Status_{KX}* bit is set.

Access to segments with a minimum privilege level of SUPERVISOR are allowed when the processor is operating with SUPERVISOR privilege and the *Status_{SX}* bit is set.

Access to segments with a minimum privilege level of USER are allowed when the processor is operating with USER privilege and the *Status_{UX}* bit is set.

[Figure 9.18](#) shows the format of the *SegCtl0* Register.

Figure 9.20 SegCtl2 Register Format (CP0 Register 5, Select 4)**Table 9.26 SegCtl2 Register Field Descriptions**

Fields		Description	Read / Write	Reset State
Name	Bits			
XR	63..56	xkphys region access mode enable. Each bit of XR[0..7] defines access mode enable for the corresponding region of the xkphys segment.	R/W	0
CFG 5	31..16	Segment Configuration 5, see Table 9.28	R/W	Implementation Dependent
CFG 4	15..0	Segment Configuration 4, see Table 9.28	R/W	

9.18.1 xkphys access mode override

The *SegCtl1XAM* and *SegCtl2XR* fields allow region selectable redefinition of the default kernel-unmapped access mode used by xkphys regions. An xkphys region *n* with associated bit *SegCtl2XR[n]*=1 uses the access mode specified by *SegCtl1XAM*. Thereby mapped xkphys regions use CCA information from the TLB. For regions where *SegCtl2XR[n]*=0, default xkphys behavior is operational.

The *SegCtl2XR* field defines an enable bit for each xkphys region (xkphys consists of $8 \cdot 2^{\text{PABITS}}$ byte regions within the 2^{62} byte xkphys segment). The xkphys regions are indexed 0..7 in ascending address order in the *SegCtl2XR* field.

On reset, the *SegCtl1XAM* field is undefined and the *SegCtl2XR* field is set to zero. This behavior is designed to be backward compatible with legacy microMIPS64 systems.

[Table 9.27](#) describes the XR indexing of the microMIPS64 xkphys address space.

Table 9.27 XR indexing of MIPS64 xkphys address regions

XR	SegCtl2 _{63..56}	Virtual Address range
7	63	0xBFFF FFFF FFFF FFFF through 0xB800 0000 000 0000
6	62	0xB7FF FFFF FFFF FFFF through 0xB000 0000 000 0000
5	61	0xAFFF FFFF FFFF FFFF through 0xA800 0000 000 0000

Table 9.27 XR indexing of MIPS64 xkphys address regions (Continued)

XR	SegCtl2 _{63..56}	Virtual Address range
4	60	0xA7FF FFFF FFFF FFFF through 0xA000 0000 000 0000
3	59	0x9FFF FFFF FFFF FFFF through 0x9800 0000 000 0000
2	58	0x97FF FFFF FFFF FFFF through 0x9000 0000 000 0000
1	57	0x8FFF FFFF FFFF FFFF through 0x8800 0000 000 0000
0	56	0x87FF FFFF FFFF FFFF through 0x8000 0000 0000 0000

Table 9.28 describes the CFG (Segment Configuration) fields defined in all CFG fields of the Segmentation Control registers.

Table 9.28 CFG (Segment Configuration) Field Description

Fields		Description	Read / Write	Compliance
Name	Bits			
PA	15..9	Physical address bits for Segment, for use when unmapped. See Section 4.13 “Segmentation Control” . This field is provisioned to support mapping of up to a 36-bit physical address.	R/W	Required
0	8..7	Reserved.	R0	Required
AM	6..4	Access control mode. See Table 9.29 .	R/W	Required
EU	3	Error condition behavior. Segment becomes unmapped and uncached when <i>Status_{ERL}</i> =1.	R/W	Required
C	2..0	Cache coherency attribute, for use when unmapped. As defined by base architecture. See Table 9.11 on page 150 for the encoding of this field. For Release 6, writes of unsupported values leave the field unmodified, whereas in Release 5, such a write may result in UNDEFINED behavior.	R/W	Required

Table 9.29 describes the access control modes specifiable in the CFG_{AM} field.

Table 9.29 Segment Configuration Access Control Modes

Mode		Action when referenced from Operating Mode			Description
		User mode	Supervisor mode	Kernel mode	
UK	000	Address Error	Address Error	Unmapped	Kernel-only unmapped region e.g. kseg0, kseg1
MK	001	Address Error	Address Error	Mapped	Kernel-only mapped region e.g. kseg3
MSK	010	Address Error	Mapped	Mapped	Supervisor and kernel mapped region e.g. ksseg, sseg
MUSK	011	Mapped	Mapped	Mapped	User, supervisor and kernel mapped region e.g. useg, kuseg, suseg
MUSUK	100	Mapped	Mapped	Unmapped	Used to implement a fully-mapped flat address space in user and supervisor modes, with unmapped regions which appear in kernel mode.
USK	101	Address Error	Unmapped	Unmapped	Supervisor and kernel unmapped region e.g. sseg in a fixed mapping TLB.
UUSK	111	Unmapped	Unmapped	Unmapped	Unrestricted unmapped region

Table 9.30 describes a configuration of Segmentation Control equivalent to legacy fixed partitioning. This is a recommended reset configuration for conformance with legacy fixed segmentation.

Table 9.30 Segment Configuration (32-bit Compatibility Region) legacy reset state

CFG	Segment	AM	PA	C	EU
0	kseg3	MK	Undefined	Undefined	0
1	ksseg, sseg	MSK	Undefined	Undefined	0
2	kseg1	UK	0x000	2	0
3	kseg0	UK	0x000	3	0
4	kuseg, suseg, useg	MUSK	0x002	Undefined	1
5	kuseg, suseg, useg	MUSK	0x000	Undefined	1

9.19 PWBase Register (CP0 Register 5, Select 5)

Compliance Level: *Required* for the hardware page walker feature.

The *PWBase* register contains the Page Table Base virtual address, used as the starting point for hardware page table walking. It is used in combination with the *PWField* and *PWSize* registers.

The *PWBase* register is instantiated per-VPE in an MT Module processor.

The existence of this register is denoted when *Config3_{PW}*=1.

The operation of page table walking is described in [Section 4.15 “Hardware Page Table Walker”](#).

[Figure 9.21](#) shows the format of the *PWBase* register; [Table 9.32](#) describes the *PWBase* register fields.

Figure 9.21 PWBase Register Format

Table 9.32 PWBase Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
PWBase	63..0	Page Table Base address pointer	R/W	0	Required

9.20 PWField Register (CP0 Register 5, Select 6)

Compliance Level: *Required* for the hardware page walker feature.

The *PWField* register configures hardware page table walking for TLB refills. It is used in combination with the *PWBase* and *PWSize* registers.

The hardware page walker feature supports multi-level page tables - up to four directory levels plus one page table level. The lowest level of any page table system is an array of Page Table Entries (PTEs). This array is known as a Page Table (PT) and is indexed using bits from the faulting address. A single-level page table system contains only a single Page Table.

A multi-level page table system forms a tree structure - the lowest (leaf) elements of which are Page Table Entries. Levels above the lowest Page Table level are known as Directories. A directory consists of an array of pointers. Each pointer in a directory is either to another directory or to a Page Table.

The Page Table and the Directories are indexed by bits extracted from the faulting address. The *PWBase* register contains the base address of the first Directory or Page Table which will be accessed. The *PWSize* register specifies the number of index bits to be used for each level. The *PWField* register specifies the location of the index fields in the faulting address.

This register only exists if *Config3_{PW}*=1.

The *PWField* register is instantiated per-VPE in an MT Module processor.

If a synchronous exception condition is detected on a read operation during hardware page-table walking, the automated process is aborted and a TLB or XTLB Refill exception is taken.

[Figure 9.22](#) shows the formats of the *PWField* Register; [Table 9.33](#) describes the *PWField* register fields.

Figure 9.22 PWField Register Format

Table 9.33 PWField Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
0	63..38	Must be written as zero; returns zero on read.	R0	0	Optional
BDI	37..32	Base Directory index. Least significant bit of the index field extracted from the faulting address, which is used to index into the Base Directory. The number of index bits is specified by $PWSize_{BDW}$. Release 6: Entire write is dropped if the write value to this field is less than 12. Release 6: BDI is read-only 0 if $PWCtl_{PWDirExt}=0$	R/W or R0	0	Optional
0	31..30	Must be written as zero; returns zero on read.	R0	0	Required
GDI	29..24	Global Directory index. Least significant bit of the index field extracted from the faulting address, which is used to index into the Global Directory. The number of index bits is specified by $PWSize_{GDW}$. Release 6: Entire write is dropped if the write value to this field is less than 12.	R/W	0 (Pre-Release 6) 12 (Release 6)	Required when $PWSize_{GDW}$ is implemented
UDI	23..18	Upper Directory index. Least significant bit of the index field extracted from the faulting address, which is used to index into the Upper Directory. The number of index bits is specified by $PWSize_{UDW}$. Release 6: Entire write is dropped if the write value to this field is less than 12.	R/W	0 (Pre-Release 6) 12 (Release 6)	Required when $PWSize_{UDW}$ is implemented
MDI	17..12	Middle Directory index. Least significant bit of the index field extracted from the faulting address, which is used to index into the Middle Directory. The number of index bits is specified by $PWSize_{MDW}$. Release 6: Entire write is dropped if the write value to this field is less than 12.	R/W	0 (Pre-Release 6) 12 (Release 6)	Required when $PWSize_{MDW}$ is implemented
PTI	11..6	Page Table index. Least significant bit of the index field extracted from the faulting address, which is used to index into the Page Table. The number of index bits is specified by $PWSize_{PTW}$. Release 6: Entire write is dropped if the write value to this field is less than 12. If PTI is not a power of four, the pagesize is downgraded to the nearest power of four.	R/W	0 (Pre-Release 6) 12 (Release 6)	Required

Table 9.33 PWField Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
PTEI	5..0	<p>Page Table Entry shift. Specifies the logical right shift and rotation which will be applied to Page Table Entry values loaded by hardware page table walking.</p> <p>The entire PTE is logically right shifted by <i>PTEI</i>-2 bits first. The purpose of this shift is to remove the SW-only bits from what will be written into the TLB entry. Then the two least-significant bits of the shifted value are rotated into position for the RI and XI protection bit locations within the TLB entry.</p> <p>A value of 2 means rotate the right-most two bits into the RI/XI bit positions for the TLB entry.</p> <p>A value of 3 means logical shift right by one bit the entire PTE and then rotate the right-most two bits into the RI/XI positions for the TLB entry. A value of 4 means logical shift right by two bits the entire PTE and then rotate the right-most two bits into the RI/XI positions for the TLB entry.</p> <p>For Pre-Release 6, the values of 1 and 0 are RESERVED and should not be used; the operation of the HW Page Walker is UNPREDICTABLE for these cases.</p> <p>For Release 6, a write of an unsupported value leaves the register unmodified. Values of 0,1 are unsupported, 2 is required, and all other values are optional and implementation-specific.</p> <p>Software can discover the available values by writing this field. If the requested shift value is not available, <i>PTEI</i> will remain unchanged.</p>	R/W	2	Required

The *PWField* register may be optionally extended to a 64 bit register to include support for an additional 4th directory level prior to PGD (*PWField_{BDI}*). With this additional level, the length of the page table walk increases to 5 levels from 4. The *PWCtl_{PWDirExt}* field is used by Software to determine the presence of this feature.

The purpose of this additional level is to support walking multiple tables. For example, user and kernel page tables can be maintained separately.

Note that the *PTEI* field can be incorrectly programmed so that the entire PFN, C, V, G TLB fields are overwritten with zeros by the logical right shift operation. The intention of this facility is to only remove the SW-only bits of the PTE from the value which will be later written into the TLB.

9.21 PWSIZE Register (CP0 Register 5, Select 7)

Compliance Level: *Required* for the hardware page walk feature.

The *PWSIZE* register configures hardware page table walking for TLB refills. It is used in combination with the *PWBase* and *PWField* registers.

The operation of page table walking is described in [Section 4.15 “Hardware Page Table Walker”](#).

The hardware page walk feature supports multi-level page tables - up to four directory levels plus one page table level. The lowest level of any page table system is an array of Page Table Entries (PTEs). This array is known as a Page Table (PT) and is indexed using bits from the faulting address. A single-level page table system contains only a single Page Table.

A multi-level page table system forms a tree structure - the lowest (leaf) elements of which are Page Table Entries. Levels above the lowest Page Table level are known as Directories. A directory consists of an array of pointers. Each pointer in a directory is either to another directory or to a Page Table.

The Page Table and the Directories are indexed by bits extracted from the faulting address *BadVAddr*. The *PWBase* register contains the base address of the first Directory or Page Table which will be accessed. The *PWSIZE* register specifies the number of index bits to be used for each level. The *PWField* register specifies the location of the index fields in *BadVAddr*.

Index values used to access Directories are multiplied by the native pointer size for the refill. For 32-bit addressing, the native pointer size is 32 bits (2 bit left shift). For 64-bit addressing, the native pointer size is set by the *PWSIZE_{PS}* field. When *PWSIZE_{PS}*=0, the native pointer size is 32 bits (2 bit left shift), and hardware page table walking is applied only when the TLB or XTLB Refill exception would be taken. When *PWSIZE_{PS}*=1, the native pointer size is 64 bits (3 bit left shift), and hardware page table walking is applied only when an XTLB Refill exception would be taken.

The index value used to access the Page Table is multiplied by the native pointer size. An additional multiplier (left shift value) can be specified using the *PWSIZE_{PTW}* field. This allows space to be allocated in the Page Table structure for software-managed fields.

This register only exists if *Config3_{PW}*=1.

The *PWSIZE* register is instantiated per-VPE in an MT Module processor.

[Figure 9.23](#) shows the formats of the *PWSIZE* Register; [Table 9.34](#) describes the *PWSIZE* register fields.

Figure 9.23 PWSize Register Format

Table 9.34 PWSize Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance						
Name	Bits										
0	63..38	Must be written as zero; returns zero on read.	0	0	Optional						
BDW	37..32	Base Directory index width. Pointers within Directories are loaded as 64-bit addresses. Hardware Page Table Walking is activated only for 64-bit address regions, when the TLB/XTLB Refill vector would be used.	R/W	0	Required
Value	Meaning										
0	32-bit pointer size. Pointers within Directories are loaded as 32-bit addresses. Hardware Page Table Walking is activated only for 32-bit address regions, when the TLB Refill vector would be used.										
1	64-bit pointer size. Pointers within Directories are loaded as 64-bit addresses. Hardware Page Table Walking is activated only for 64-bit address regions, when the TLB/XTLB Refill vector would be used.										

Table 9.34 PWSize Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance	
Name	Bits					
GDW	29..24	Global Directory index width.	R/W	0	Recommended	
		Value				Meaning
		0				No read is performed using Global Directory index.
		Non-zero				Number of bits to be extracted from <i>BadVAddr</i> to create an index into the Global Directory. The least significant bit of the field is specified by <i>PWField_{GDI}</i> .
UDW	23..18	Upper Directory index width.	R/W	0	Recommended	
		Value				Meaning
		0				No read is performed using Upper Directory index.
		Non-zero				Number of bits to be extracted from <i>BadVAddr</i> to create an index into the Upper Directory. The least significant bit of the field is specified by <i>PWField_{UDI}</i> .
MDW	17..12	Middle Directory index width.	R/W	0	Recommended	
		Value				Meaning
		0				No read is performed using Middle Directory index.
		Non-zero				Number of bits to be extracted from <i>BadVAddr</i> to create an index into the Middle Directory. The least significant bit of the field is specified by <i>PWField_{MDI}</i> .
PTW	11..6	Page Table index width. Value 0 meaning has changed for Release 6.	R/W	0 (Pre-Release 6) 1 (Release 6)	Required	
		Value				Meaning
		0				Pre-Release 6: UNPREDICTABLE Release 6: Write of 0 is ignored; entire write is dropped.
		Non-zero				Number of bits to be extracted from <i>BadVAddr</i> to create an index into the Page Table. The least significant bit of the field is specified by <i>PWField_{PTI}</i> .

Table 9.34 PWSize Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
PTEW	5..0	Specifies the left shift applied to the Page Table index, in addition to the shift required to account for the native data size of the machine. The set of available shifts is implementation-dependent. Software can discover the available values by writing this field. If the requested shift value is not available, PTEW will be written as zero. A shift of one must be implemented. In Release 6, if $PWSize_{PS} = 1$, then it is implementation-dependent as to whether PTEW is writeable, or read-only 0. PTE sizes of 128-bits are not recommended.	R/W	0	Required

The $PWSize$ register may be optionally extended to a 64 bit register to include support for an additional 4th directory level prior to PGD ($PWSize_{BDW}$). With this additional level, the length of the page table walk increases to 5 levels from 4. The $PWCtrl_{PDirExt}$ field is used by Software to determine the presence of this feature.

Table 9.35 describes valid $PWSize_{PS/PTEW}$ and $PWCtrl_{HugePg}$ settings. Whether the case $PWSize_{PS}=1$ & $PWSize_{PTEW}=1$ is supported is implementation-dependent as specified in description for $PWSize_{PTEW}$.

Table 9.35 PS/PTEW Usage

$PWSize_{PS}$	$PWCtrl_{HugePg}$	$PWSize_{PTEW}$	Pointer Addressing	Directory Pointer Size	Non-Leaf PTE Size	Leaf PTE Size	Suggested Use Case
0	0	0	32 bits	32 bits	N/A	32 bits	32-bit Compatibility
0	0	1	32 bits	32 bits	N/A	64 bits	32-bit with PA>32bits Compatibility
0	1	0	32 bits	32 bits	32 bits	32 bits	32-bit with Huge Pages Compatibility
0	1	1	32 bits	64 bits ¹	64 bits	64 bits	32-bit with Huge Pages & PA>32 bits Compatibility
1	0	0	64 bits	64 bits	N/A	64 bits	64-bit Base
1	0	1	64 bits	64 bits	N/A	128 bits	64-bit with extended PTE
1	1	0	64 bits	64 bits	64 bits	64 bits	64 bit with Huge Pages
1	1	1	64 bits	128 bits ¹	128 bits	128 bits	64-bit with Huge Pages & extended PTE

Table 9.35 PS/PTEW Usage (Continued)

<i>PWSIZE_{PS}</i>	<i>PWCTL_{HugePg}</i>	<i>PWSIZE_{PTEW}</i>	Pointer Addressing	Directory Pointer Size	Non-Leaf PTE Size	Leaf PTE Size	Suggested Use Case
N/A	N/A	>1					Not supported

1. The “Directory Pointer Size” column denotes how many bytes of memory is used for each pointer in the directory levels. If this size is larger than the pointer itself, the pointer uses the least significant bytes.

64-bit architectural support of 32-bit and/or 64-bit compatibility/extended modes is implementation-dependent. Software can determine supported modes by writing to *PWSIZE_{PS}* and *PWSIZE_{PTEW}* fields and reading, unsupported values will be written as zero.

9.22 Wired Register (CP0 Register 6, Select 0)

Compliance Level: *Required* for TLB-based MMUs; *Optional* otherwise.

The *Wired* register is a read/write register that specifies the boundary between the wired and random entries in the TLB as shown in [Figure 9.24](#).

Figure 9.24 Wired And Random Entries In The TLB

The width of the *Wired* field is calculated in the same manner as that described for the *Index* register. *Wired* entries are fixed, non-replaceable entries which are not overwritten by a TLBWR instruction. *Wired* entries can be overwritten by a TLBWI instruction.

The *Wired* register is set to zero by a Reset Exception. Writing the *Wired* register causes the *Random* register to reset to its upper bound.

The operation of the processor is **UNDEFINED** if a value greater than or equal to the number of TLB entries is written to the *Wired* register.

Release 6 adds the *Limit* field. The intent of a non-zero value for this field is to place a limit on the number of wired entries in a TLB such that non-wired entries may be shared in a common physical TLB by multiple VPEs (as defined in the Multi-threading (MT) Module, Volume IV-f), or Guests and Root (see the Virtualization Module, Volume IV-i). For Release 6, if the Limit field is greater than 0, and a value greater than Limit is written to the *Wired* field, then the write is ignored.

A Reset Exception does not impact the state of *Limit*.

In Release 6, the *Random* register is no longer supported.

[Figure 9.24](#) shows the format of the *Wired* register; [Table 9.36](#) describes the *Wired* register fields.

Figure 9.25 Wired Register Format

Table 9.36 Wired Register Field Descriptions

Fields		Description	Read/ Write	Reset State	Compliance						
Name	Bits										
0	31..m	Must be written as zero; returns zero on read. The size of this field is determined by <i>Limit</i> .	0	0	Reserved						
Limit	m-1..16	<p>TLB wired limit - see table below.</p> <p>Wired entries are only applicable to a variable-sized TLB, such as when <i>Config_{MT}</i>=1 or 4. A fixed-size TLB in the case of <i>Config_{MT}</i>=4 does not have wired entries.</p> <p><i>Limit</i> may alternatively be programmed but only as specified by the contents of an implementation-dependent register i.e., this capability is not architecturally visible.</p> <p>Attempting to write a value greater than Limit into the Wired field causes the write to be dropped.</p> <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>Pre Release 6 compatibility. The maximum number of wired entries may be equal to the number of TLB entries minus one. The field is reserved i.e., writes are ignored, reads return 0s.</td></tr><tr><td>> 0</td><td>The maximum number of wired entries, which must be less than the number of TLB entries minus one. The number of wired entries is implementation-dependent and is equal to <i>Limit</i>.</td></tr></table>	Encoding	Meaning	0	Pre Release 6 compatibility. The maximum number of wired entries may be equal to the number of TLB entries minus one. The field is reserved i.e., writes are ignored, reads return 0s.	> 0	The maximum number of wired entries, which must be less than the number of TLB entries minus one. The number of wired entries is implementation-dependent and is equal to <i>Limit</i> .	R	Preset by hardware	Required (Release 6)
Encoding	Meaning										
0	Pre Release 6 compatibility. The maximum number of wired entries may be equal to the number of TLB entries minus one. The field is reserved i.e., writes are ignored, reads return 0s.										
> 0	The maximum number of wired entries, which must be less than the number of TLB entries minus one. The number of wired entries is implementation-dependent and is equal to <i>Limit</i> .										
0	15..n	Must be written as zero; returns zero on read. The size of this field is determined by <i>Wired</i> .	0	0	Reserved						
Wired	n-1..0	TLB wired boundary	R/W	0	Required						

9.23 PWCtl Register (CP0 Register 6, Select 6)

Compliance Level: *Required* for the hardware page walker feature.

The *PWCtl* register configures hardware page table walking for TLB refills. It is used in combination with the *PWBase*, *PWField* and *PWSize* registers.

Hardware page table walking is disabled when *PWCtl*_{PWEn}=0.

The hardware page walker feature supports multi-level page tables - up to four directory levels plus one page table level. The lowest level of any page table system is an array of Page Table Entries (PTEs). This array is known as a Page Table (PT) and is indexed using bits from the faulting address. A single-level page table system contains only a single Page Table.

A multi-level page table system forms a tree structure - the lowest (leaf) elements of which are Page Table Entries. Levels above the lowest Page Table level are known as Directories. A directory consists of an array of pointers. Each pointer in a directory is either to another directory or to a Page Table.

The Page Table and the Directories are indexed by bits extracted from the faulting address *BadVAddr*. The *PWBase* register contains the base address of the first Directory or Page Table which will be accessed. The *PWSize* register specifies the number of index bits to be used for each level. The *PWField* register specifies the location of the index fields in *BadVAddr*.

The existence of this register is denoted when *Config3*_{PW}=1.

The *PWField* register is instantiated per-VPE in an MT Module processor.

Figure 9.26 shows the formats of the *PWCtl* Register; Table 9.37 describes the *PWCtl* register fields.

Figure 9.26 PWCtl Register Format

31	30	29	28	27	26	25		8	7	6	5..0
PWEn	PWDirExt	0	XK	XS	XU	Reserved			DPH	HugePg	PsN

Table 9.37 PWCtl Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
PWEn	31	Hardware Page Table walker enable If this bit is set, then the Hardware Page Table is enabled.	R/W	0	Required
PWDirExt	30	PW Indices - <i>PWField</i> and <i>PWSize</i> - extended for 4th directory level - the Base level. In Release 6, PWDirExt may be read-only 0. If read-only 0, then Base Directory is not supported.	R/W or R0	0	Required
XK	28	If <i>XK</i> =1, walker handles xkseg. If <i>XK</i> =0, xkseg misses generate a TLB miss exception. The hardware page walk is not initiated.	R/W	0	Required
XS	27	If <i>XS</i> =1, walker handles xsseg. If <i>XS</i> =0, xsseg misses generate a TLB miss exception. The hardware page walk is not initiated.	R/W	0	Required
XU	26	If <i>XU</i> =1, walker handles xuseg. If <i>XU</i> =0, xuseg misses generate a TLB miss exception. The hardware page walk is not initiated.	R/W	0	Required
-	29, 25..8	Reserved, Must be written as zero; returns zero on read.	R0	0	Required
DPH	7	Dual Page format of Huge Page support. This bit is only used when <i>HugePg</i> =1. If <i>DPH</i> bit is set, then a Huge Page PTE can represent a power-of-4 memory region or a 2x power-of-4 memory region. For the first case, one PTE is used for even TLB page and the adjacent PTE is used for the odd PTE. For the latter case, the Hardware will synthesize the physical addresses for both the even and odd TLB pages from the single PTE entry. If <i>DPH</i> bit is clear, then a Huge Page PTE can only represent a region that is 2 x power-of-4 in size. For this case, the Hardware will synthesize the physical addresses for both the even and odd TLB pages from the single PTE entry.	R or R/W	0	Required
HugePg	6	Huge Page PTE supported in Directory levels. If this bit is set, then Huge Page PTE in non-leaf table (i.e., directory level) is supported.	R or R/W	0	Required
PSn	5:0	Bit position of <i>PTeVld</i> in Huge Page PTE. Only used when <i>HugePg</i> field is set.	R/W	0	Required

*PWCtl*_{XKXSXU} are considered a single field - if the value of the 3-bits in the MTC0 write data is reserved, then the entire write is dropped.

If the implementation supports Huge Pages, then Software enables Huge Pages by setting $PWCTL_{HugePg}=1$. Software can disable Huge Pages by setting $PWCTL_{HugePg}=0$. An implementation that does not support Huge Pages is required to hardwire $PWCTL_{HugePg}=0$ read-only. Software can determine Huge Page support by writing 1 to $PWCTL_{HugePg}$, if a following read returns 0, then Huge Page support is not implemented.

The $PWCTL_{Psn}$ field is provisioned at 6 bits, allowing a starting bit position for PTE_{vld} up to bit 64 in the PTE. An implementation may choose to support a more limited range by hardwiring an implementation defined number of the high order bits of $PWCTL_{Psn}$ to 0. Software can determine the supported range by writing ones to $PWCTL_{Psn}$ then reading.

Table 9.38 describes allowed $PWCTL_{XK/XS/XU}$ register field configurations.

Table 9.38 PWCtl XK/XS/XU Register Field configurations

Fields			Virtual Address Bits Prepended to Global Directory Index	Hardware walker capability
XK	XS	XU		
0	0	0	None	disabled
0	0	1	None	xuseg
0	1	0	-	reserved
0	1	1	62	xuseg and xsseg
1	0	0	-	reserved
1	0	1	63	xuseg and xkseg
1	1	0	-	reserved
1	1	1	63..62	xuseg, xsseg, xkseg

The XK , XS , XU fields of the $PWCTL$ register control visibility of virtual address bits 63..62 specified in $PWFieldGDI$ and $PWSizeGDW$. The XK , XS , XU fields function primarily as a performance optimization, allowing segment based exclusion of address translations from the hardware page table.

The XK , XS , XU fields are ignored if the optional 4th directory level feature (determinable by $PWCTL_{PWDirExt}=1$) is implemented, in this case, virtual address bits 63..62 are used in Base Directory lookup.

Table 9.39 describes how the $HugePg$ field is used to denote whether Huge Pages are supported or not.

Table 9.39 HugePg Field and Huge Page configurations

$PWCTL_{HugePg}$	Type of Entry		Rsvd Field in Non-leaf entry	Comment
	Non-Leaf	Leaf		
0	Always Pointer PTE_{PTEvld} not used	Always PTE PTE_{PTEvld} not used	X	No Huge-Page Support
1	$PTE_{PTEvld}=0$ means Pointer $PTE_{PTEvld}=1$ means Huge Page	Always PTE PTE_{PTEvld} not used	Must be 0	Huge-Page Support

Table 9.40 describes how Huge Pages are represented in the Directory Levels.

Table 9.40 Huge Page representation in Directory Levels

PWCTL _{DPH}	Size of Huge Page		Comment
	Power of 4	non-Power of 4	
0	Not Allowed If encountered, HW Page Walker aborts and TLB/XTLB Refill exception is taken.	Allowed Even TLB page and Odd TLB page entries both derived from single PTE	Huge-Page region can only be 2x power-of-4
1	Allowed Two PTEs are read from memory by the HW Page Walker to be used for the Even and Odd TLB page entries.	Allowed Even TLB page and Odd TLB page entries both derived from single PTE	Huge-Page region can be any power-of- 2 (either power of 4 or 2x power-of-4)

Table 9.42 RDHWR Register Numbers

Register Number	Mnemonic	Description	Compliance										
0	CPUNum	Number of the CPU on which the program is currently running. This register provides read access to the coprocessor 0 <i>EBase</i> _{CPUNum} field.	Required										
1	SYNCL_Step	Address step size to be used with the SYNCL instruction. See that instruction’s description for the use of this value. In the typical implementation, this value should be zero if there are no caches in the system which must be synchronize (either because there are no caches, or because the instruction cache tracks writes to the data cache). In other cases, the return value should be the smallest line size of the caches that must be synchronize.	Required										
2	CC	High-resolution cycle counter. This register provides read access to the coprocessor 0 <i>Count</i> Register.	Required										
3	CCRes	Resolution of the CC register. This value denotes the number of cycles between update of the register. For example: <table><tr><th>CCRes Value</th><th>Meaning</th></tr><tr><td>1</td><td>CC register increments every CPU cycle</td></tr><tr><td>2</td><td>CC register increments every second CPU cycle</td></tr><tr><td>3</td><td>CC register increments every third CPU cycle</td></tr><tr><td colspan="2">etc.</td></tr></table>	CCRes Value	Meaning	1	CC register increments every CPU cycle	2	CC register increments every second CPU cycle	3	CC register increments every third CPU cycle	etc.		Required
CCRes Value	Meaning												
1	CC register increments every CPU cycle												
2	CC register increments every second CPU cycle												
3	CC register increments every third CPU cycle												
etc.													
4	PerfCnt	Performance Counter Pair. Even <i>sel</i> selects the <i>Control</i> register, while odd <i>sel</i> selects the <i>Counter</i> register in the pair.	Required if any <i>PerfCnt</i> register is implemented (Release 6)										
5	XNP	Indicates support for Release 6 Double-Width LLX/SCX family of instructions. If set to 1, then LLX/SCX family of instructions is not present, otherwise present in the implementation. In absence of hardware support for double-width or extended atomics, user software may emulate the instruction’s behavior through other means. See <i>Config5</i> _{XNP} .	Required (Release 6)										
6-28		These registers numbers are reserved for future architecture use. Access results in a Reserved Instruction Exception.	Reserved										
29	ULR	User Local Register. This register provides read access to the coprocessor 0 <i>UserLocal</i> register, if it is implemented. In some operating environments, the <i>UserLocal</i> register is a pointer to a thread-specific storage block. In Release 6, the <i>UserLocal</i> register is required.	Required if the <i>UserLocal</i> register is implemented										
30-31		These register numbers are reserved for implementation-dependent use. If they are not implemented, access results in a Reserved Instruction Exception.	Optional										

Using the *HWREna* register, privileged software may select which of the hardware registers are accessible via the RDHWR instruction. In doing so, a register may be virtualized at the cost of handling a Reserved Instruction Exception, interpreting the instruction, and returning the virtualized value. For example, if it is not desirable to provide direct access to the *Count* register, access to that register may be individually disabled and the return value can be virtualized by the operating system.

Software may determine which registers are implemented by writing all ones to the *HWREna* register, then reading the value back. If a bit reads back as a one, the processor implements that hardware register.

9.25 BadVAddr Register (CP0 Register 8, Select 0)

Compliance Level: *Required.*

The *BadVAddr* register is a read-only register that captures the most recent virtual address that caused one of the following exceptions:

- Address error (AdEL or AdES)
- TLB/XTLB Refill
- TLB Invalid (TLBL, TLBS)
- TLB Modified

The *BadVAddr* register does not capture address information for cache or bus errors, or for Watch exceptions, since none is an addressing error.

Figure 9.28 shows the format of the *BadVAddr* register; Table 9.43 describes the *BadVAddr* register fields.

Figure 9.28 BadVAddr Register Format

Table 9.43 BadVAddr Register Field Descriptions

Fields		Description	Read/ Write	Reset State	Compliance
Name	Bits				
BadVAddr	63..0	Bad virtual address	R	Undefined	Required

9.26 BadInstr Register (CP0 Register 8, Select 1)

Compliance Level: Pre-Release 6 - *Optional*
Release 6 - *Required*

The *BadInstr* register is a read-only register that capture the most recent instruction which caused one of the following exceptions:

- Instruction validity

Coprocessor Unusable, Reserved Instruction

- Execution Exception

Integer Overflow, Trap, System Call, Breakpoint, Floating-Point, Coprocessor 2 exception

- Addressing

Address Error, TLB or XTLB Refill, TLB Invalid, TLB Read Inhibit, TLB Execute Inhibit, TLB Modified

The *BadInstr* register is provided to allow acceleration of instruction emulation. The *BadInstr* register is only set by exceptions which are synchronous to an instruction. The *BadInstr* register is not set by Interrupts, NMI, Machine check, Bus Error or Cache Error exceptions. The *BadInstr* register is not set by Watch or EJTAG exceptions.

When a synchronous exception occurs for which there is no valid instruction word (for example TLB Refill - Instruction Fetch), the value stored in *BadInstr* is **UNPREDICTABLE**.

Presence of the *BadInstr* register is indicated by the *Config3_{BI}* bit set to 1. The *BadInstr* register is instantiated per-VPE in an MT Module processor. For Release 6, the *Config3_{BI}* bit must always be set to 1.

Figure 9.29 shows the proposed format of the *BadInstr* register; Table 9.44 describes the *BadInstr* register fields.

Figure 9.29 BadInstr Register Format

Table 9.44 BadInstr Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
BadInstr	31:0	Faulting instruction word. Instruction words smaller than 32 bits are placed in bits 15:0, with bits 31:16 containing zero.	R	Undefined	Optional (Pre-Release 6) Required (Release 6)

9.27 BadInstrP Register (CP0 Register 8, Select 2)

Compliance Level: Pre-Release 6 - *Optional*
Release 6 - *Required*

The *BadInstrP* register is used in conjunction with the *BadInstr* register. The *BadInstrP* register contains the prior branch instruction, when the faulting instruction is in a branch delay slot.

The *BadInstrP* register is updated for these exceptions:

- Instruction validity
Coprorocessor Unusable, Reserved Instruction
- Execution Exception
Integer Overflow, Trap, System Call, Breakpoint, Floating-Point, Coprocessor 2 exception
- Addressing
Address Error, TLB or XTLB Refill, TLB Invalid, TLB Read Inhibit, TLB Execute Inhibit, TLB Modified

The *BadInstrP* register is provided to allow acceleration of instruction emulation. The *BadInstrP* register is only set by exceptions which are synchronous to an instruction. The *BadInstrP* register is not set by Interrupts, NMI, Machine check, Bus Error or Cache Error exceptions. The *BadInstr* register is not set by Watch or EJTAG exceptions.

When a synchronous exception occurs and the faulting instruction is not in a branch delay slot, then the value stored in *BadInstrP* is **UNPREDICTABLE**.

Presence of the *BadInstrP* register is indicated by the *Config3BP* bit set to 1. The *BadInstrP* register is instantiated per-VPE in an MT Module processor. For Release 6, the *Config3BP* bit must be set to 1.

Figure 9.30 shows the proposed format of the *BadInstrP* register; Table 9.45 describes the *BadInstrP* register fields.

Figure 9.30 BadInstrP Register Format

Table 9.45 BadInstrP Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
BadInstrP	31:0	Prior branch instruction. Instruction words smaller than 32 bits are placed in bits 15:0, with bits 31:16 containing zero.	R	Undefined	Optional (Pre-Release 6) Required (Release 6)

9.28 Count Register (CP0 Register 9, Select 0)

Compliance Level: *Required.*

The *Count* register acts as a timer, incrementing at a constant rate, whether or not an instruction is executed, retired, or any forward progress is made through the pipeline. The rate at which the counter increments is implementation-dependent, and is a function of the pipeline clock of the processor, not the issue width of the processor.

The *Count* register can be written for functional or diagnostic purposes, including at reset or to synchronize processors.

The Count register can also be read via RDHWR register 2.

Figure 9.31 shows the format of the *Count* register; Table 9.46 describes the *Count* register fields.

Figure 9.31 Count Register Format

Table 9.46 Count Register Field Descriptions

Fields		Description	Read/ Write	Reset State	Compliance
Name	Bits				
Count	31..0	Interval counter	R/W	Undefined	Required

9.29 Reserved for Implementations (CP0 Register 9, Selects 6 and 7)

Compliance Level: *Implementation-dependent.*

CP0 register 9, Selects 6 and 7 are reserved for implementation-dependent use and are not defined by the architecture.

9.30 EntryHi Register (CP0 Register 10, Select 0)

Compliance Level: *Required* for TLB-based MMU; *Optional* otherwise.

The *EntryHi* register contains the virtual address match information used for TLB read, write, and access operations.

A TLB exception (TLB Refill, XTLB Refill, TLB Invalid, or TLB Modified) causes the bits of the virtual address corresponding to the *R* and *VPN2* fields to be written into the *EntryHi* register. An implementation of Release 2 of the Architecture which supports 1 kB pages also writes $VA_{12..11}$ into the *VPN2X* field of the *EntryHi* register. A TLBR instruction writes the *EntryHi* register with the corresponding fields from the selected TLB entry. The *ASID* field is written by software with the current address space identifier value and is used during the TLB comparison process to determine TLB match.

Because the *ASID* field is overwritten by a TLBR instruction, software must save and restore the value of *ASID* around use of the TLBR. This is especially important in TLB Invalid and TLB Modified exceptions, and in other memory management software.

In Release 3 of the architecture, the *VPN2* field of the TLB entry can be optionally invalidated. When this is done, the invalidated entry is ignored on address match for memory accesses. One method of invalidating the *VPN2* field is the use of the *EHINV* field with the TLBWI instruction. This field exists if *Config4_{IE}* is set to a value of 2 or 3. This field is overwritten by a TLBR instruction, so software must save and restore the value of the *EHINV* field around the use of the TLBR instruction. This is especially important for the subsequent usage of TLBWI instructions.

Software may determine the value of *SEGBITS* by writing all ones to the *EntryHi* register and reading the value back. Bits read as “1” from the *VPN2* field allow software to determine the boundary between the *VPN2* and *Fill* fields to calculate the value of *SEGBITS*.

The *VPN2X*, *VPN2*, and *R* fields of the *EntryHi* register are not defined after an address error exception and these fields may be modified by hardware during the address error exception sequence. Software writes of the *EntryHi* register (via MTC0 or DMTC0) do not cause the implicit write of address-related fields in the *BadVAddr*, *Context*, or *XContext* registers.

Figure 9.32 shows the format of the *EntryHi* register; Table 9.47 describes the *EntryHi* register fields.

Figure 9.32 EntryHi Register Format

Table 9.47 EntryHi Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance										
Name	Bits														
R	63..62	<div>Virtual memory region, corresponding to $VA_{63..62}$.</div> <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0b00</td><td>xuseg: user address region</td></tr><tr><td>0b01</td><td>xsseg: supervisor address region. If Supervisor Mode is not implemented, this encoding is reserved</td></tr><tr><td>0b10</td><td>Reserved</td></tr><tr><td>0b11</td><td>xkseg: kernel address region</td></tr></table> <div>This field is written by hardware on a TLB exception or on a TLB read, and is written by software before a TLB write. For processors implementing $Config_{AT} = 1$ (access to 32-bit compatibility segments only), only the 0b00 and 0b11 values are legal. In this circumstance, the operation of the processor is UNDEFINED if $EntryHi_R$ is written with any other value, and the processor will only supply the legal values on an exception.</div>	Encoding	Meaning	0b00	xuseg: user address region	0b01	xsseg: supervisor address region. If Supervisor Mode is not implemented, this encoding is reserved	0b10	Reserved	0b11	xkseg: kernel address region	R/W	Undefined	Required
Encoding	Meaning														
0b00	xuseg: user address region														
0b01	xsseg: supervisor address region. If Supervisor Mode is not implemented, this encoding is reserved														
0b10	Reserved														
0b11	xkseg: kernel address region														
Fill	61..40	Fill bits reserved for expansion of the virtual address space. See below. Returns zeros on read, ignored on write.	R	0	Required										
VPN2	39..13	$VA_{39..13}$ of the virtual address (virtual page number / 2). This field is written by hardware on a TLB exception or on a TLB read, and is written by software before a TLB write. The default width of this field implicitly limits the size of each virtual address space to 40 bits. If the processor implements fewer virtual address bits than this default, the <i>Fill</i> field must be extended to take up the unimplemented <i>VPN2</i> bits. If the processor implements more virtual address bits than this default, the <i>VPN2</i> field must be extended to take up some or all of the <i>Fill</i> bits.	R/W	Undefined	Required										
VPN2X	12..11	In Release 2 of the Architecture (and subsequent releases), the <i>VPN2X</i> field is an extension to the <i>VPN2</i> field to support 1 kB pages. These bits are not writable by either hardware or software unless $Config3_{SP} = 1$ and $PageGrain_{ESP} = 1$. If enabled for write, this field contains $VA_{12..11}$ of the virtual address and is written by hardware on a TLB exception or on a TLB read, and is by software before a TLB write. If writes are not enabled, and in implementations of Release 1 of the Architecture, this field must be written with zero and returns zeros on read.	R/W	0	Required (Release 2 and 1 kB Page Support)										

Table 9.47 EntryHi Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
EHINV	10	TLB HW Invalidate If $Config4_{IE} > 1$, and this bit is set, the TLBWI instruction will invalidate the VPN2 field of the selected TLB entry. If $Config4_{IE} > 1$, a TLBR instruction will update this field with the VPN2 invalid bit of the read TLB entry.	R/W	0	Optional (Release 3). Required for TLBWI hardware invalidate support, or if $Config4_{IE}=2$ or 3. Required (Release 6)
ASIDX	9..8	If $Config4_{AE} = 1$ then these bits extend the ASID field. If $Config4_{AE} = 0$ then Must be written as zero; returns zero on read.	If $Config4_{AE} = 1$ then R/W else 0	If $Config4_{AE} = 1$ then Undefined else 0	Required
ASID	7..0	Address space identifier. This field is written by hardware on a TLB read and by software to establish the current ASID value for TLB write and against which TLB references match each entry's TLB ASID field.	R/W	Undefined	Required (TLB MMU)

Programming Note:

In implementations of Release 2 (and any subsequent releases prior to Release 6) of the Architecture, the $VPN2X$ field of the $EntryHi$ register must be written with zero and the TLB must be flushed before each instance in which the value of the $PageGrain$ register is changed. This operation must be carried out while running in an unmapped address space. The operation of the processor is **UNDEFINED** if this sequence is not done.

For Release 6, this is not a requirement because support for $EntryHi_{EHINV}$ is mandatory. Instead, software must invalidate the TLB entries explicitly using TLBWI with $EntryHi_{EHINV}=1$.

9.31 Compare Register (CP0 Register 11, Select 0)

Compliance Level: *Required.*

The *Compare* register acts in conjunction with the *Count* register to implement a timer and timer interrupt function. The *Compare* register maintains a stable value and does not change on its own.

When the value of the *Count* register equals the value of the *Compare* register, an interrupt request is made. In Release 1 of the architecture, this request is combined in an implementation-dependent way with hardware interrupt 5 to set interrupt bit *IP*(7) in the *Cause* register. In Release 2 (and subsequent releases) of the Architecture, the presence of the interrupt is visible to software via the *Cause_{TI}* bit and is combined in an implementation-dependent way with a hardware or software interrupt. For Vectored Interrupt Mode, the interrupt is at the level specified by the *IntCtl_{IP_{TI}}* field.

For diagnostic purposes, the *Compare* register is a read/write register. In normal use however, the *Compare* register is write-only. Writing a value to the *Compare* register, as a side effect, clears the timer interrupt. Figure 9.33 shows the format of the *Compare* register; Table 9.48 describes the *Compare* register fields.

Figure 9.33 Compare Register Format

Table 9.48 Compare Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
Compare	31..0	Interval count compare value	R/W	Undefined	Required

Programming Note:

In Release 2 of the Architecture, the EHB instruction can be used to make interrupt state changes visible when the *Compare* register is written. See 6.1.2.1 “Software Hazards and the Interrupt System” on page 96.

9.32 Reserved for Implementations (CP0 Register 11, Selects 6 and 7)

Compliance Level: *Implementation-dependent.*

CP0 register 11, Selects 6 and 7 are reserved for implementation-dependent use and are not defined by the architecture.

9.33 Status Register (CP Register 12, Select 0)

Compliance Level: *Required.*

The *Status* register is a read/write register that contains the operating mode, interrupt enabling, and the diagnostic states of the processor. Fields of this register combine to create operating modes for the processor. See “MIPS64 and microMIPS64 Operating Modes” on page 23 for a discussion of operating modes, and “Interrupts” on page 85 for a discussion of interrupt modes.

Figure 9.35 shows the format of the *Status* register for Pre-Release 6; Figure 9.35 shows the format of the *Status* register for Release 6; Table 9.49 describes the *Status* register fields.

Release 6 modifies the behavior of Status_{KX/SX/UX}. See Table 9.50 and the associated pseudocode for reference, in addition to Status_{KX/SX/UX}.

Figure 9.35 Status Register Format for Release 6

Table 9.49 Status Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance						
Name	Bits										
CU (CU3..CU0)	31..28	<div>Controls access to coprocessors 3, 2, 1, and 0, respectively:</div> <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>Access not allowed</td></tr><tr><td>1</td><td>Access allowed</td></tr></table> <div>Coprocessor 0 is always usable when the processor is running in Kernel Mode or Debug Mode, independent of the state of the <i>CU0</i> bit. In Release 2 (and subsequent releases) of the Architecture, and for 64-bit implementations of Release 1 of the Architecture, execution of all floating-point instructions, including those encoded with the COP1X opcode, is controlled by the <i>CU1</i> enable. <i>CU3</i> is no longer used and is reserved for future use by the Architecture. If there is no provision for connecting a coprocessor, the corresponding <i>CU</i> bit must be ignored on write and read as zero.</div>	Encoding	Meaning	0	Access not allowed	1	Access allowed	R/W	Undefined	Required for all implemented coprocessors (Pre-Release 6)
Encoding	Meaning										
0	Access not allowed										
1	Access allowed										
CU (CU3..CU1)	31..29	<div>Controls access to coprocessors 3, 2, and 1, respectively:</div> <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>Access not allowed</td></tr><tr><td>1</td><td>Access allowed</td></tr></table> <div>In Release 2 (and subsequent releases) of the Architecture, and for 64-bit implementations of Release 1 of the Architecture, execution of all floating-point instructions, including those encoded with the COP1X opcode, is controlled by the <i>CU1</i> enable. <i>CU3</i> is no longer used and is reserved for future use by the Architecture. If there is no provision for connecting a coprocessor, the corresponding <i>CU</i> bit must be ignored on write and read as zero.</div>	Encoding	Meaning	0	Access not allowed	1	Access allowed	R/W	Undefined	Required for all implemented coprocessors (Release 6)
Encoding	Meaning										
0	Access not allowed										
1	Access allowed										
RW	28	Read/write field. This bit can be written by software without side-effects. A use case is for the kernel to set this bit to signify that the exception condition is due to user code, prior to saving Status to the stack in memory.	R/W	Undefined	Required (Release 6)						
RP	27	Enables reduced power mode on some implementations. The specific operation of this bit is implementation-dependent. If this bit is not implemented, it must be ignored on write and read as zero. If this bit is implemented, the reset state must be zero so that the processor starts at full performance.	R/W	0	Optional (Pre-Release 6)						
0	27	This bit must be written as zero; returns zero on read.	0	0	Reserved (Release 6)						

Table 9.49 Status Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance						
Name	Bits										
FR	26	<p>This bit is used to control the floating-point register mode for 64-bit floating-point units:</p> <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>Floating-point registers can contain any 32-bit datatype. 64-bit datatypes are stored in even-odd pairs of registers.</td></tr><tr><td>1</td><td>Floating-point registers can contain any datatype</td></tr></table>	Encoding	Meaning	0	Floating-point registers can contain any 32-bit datatype. 64-bit datatypes are stored in even-odd pairs of registers.	1	Floating-point registers can contain any datatype	R/W (Pre-Release 6)	Undefined	Required
		Encoding	Meaning								
0	Floating-point registers can contain any 32-bit datatype. 64-bit datatypes are stored in even-odd pairs of registers.										
1	Floating-point registers can contain any datatype										
		<p>In Release 1 of the Architecture, only MIPS64 processors could implement a 64-bit floating-point unit. In Release 2 of the Architecture (and subsequent releases), both 32-bit and 64-bit processors can implement a 64-bit floating-point unit. As of Release 5 of the Architecture, if floating-point is implemented then <i>FR</i> = 1 is required. I.e. the 64-bit FPU, with the <i>FR</i> = 1 64-bit FPU register model, is required. The <i>FR</i> = 0 32-bit FPU register model continues to be required.</p> <p>Release 6 disallows bi-modal support for both 32-bit and 64-bit FPU register models in a 64-bit FPU; i.e., FR is read-only. See below for more details.</p> <p>This bit must be ignored on write and read as zero under the following conditions:</p> <ul style="list-style-type: none">• No floating-point unit is implemented• In a MIPS32 implementation of Release 1 of the Architecture• In an implementation of Release 2 of the Architecture (and subsequent releases) in which a 64-bit floating-point unit is not implemented <p>This bit must be ignored on write and read as 1 for an implementation of Release 6 of the Architecture (and subsequent releases) in which a 64-bit floating-point unit is implemented.</p> <p>Release 6 allows implementation of a 32-bit FPU with single precision support only. In this case, FR=0, although this does not imply even-odd pairing of 32-bit registers because <i>FIR_{DL}</i>=0.</p> <p>Certain combinations of the FR bit and other state or operations can cause UNPREDICTABLE behavior. See “64-bit FPR Enable” on page 25 for a discussion of these combinations.</p> <p>When software changes the value of this bit, the contents of the floating-point registers are UNPREDICTABLE.</p>	R (Release 6)	1/0

Fields		Description	Read / Write	Reset State	Compliance						
Name	Bits										
TS ¹	21	Indicates that the TLB has detected a match on multiple entries. It is implementation-dependent whether this detection occurs at all, on a write to the TLB, or an access to the TLB. In Release 2 of the Architecture (and subsequent releases), multiple TLB matches may only be reported on a TLB write. When such a detection occurs, the processor initiates a machine check exception and sets this bit. It is implementation-dependent whether this condition can be corrected by software. If the condition can be corrected, this bit should be cleared by software before resuming normal operation. See “ TLB Initialization ” on page 43 for a discussion of software TLB initialization used to avoid a machine check exception during processor initialization. If this bit is not implemented, it must be ignored on write and read as zero. Software should not write a 1 to this bit when its value is a 0, thereby causing a 0-to-1 transition. If such a transition is caused by software, it is UNPREDICTABLE whether hardware ignores the write, accepts the write with no side effects, or accepts the write and initiates a machine check exception.	R/W	0	Required if the processor detects and reports a match on multiple TLB entries (Pre-Release 6)						
0	21	This bit must be written as zero; returns zero on read.	0	0	Reserved (Release 6)						
SR	20	<div>Indicates that the entry through the reset exception vector was due to a Soft Reset:<table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>Not Soft Reset (NMI or Reset)</td></tr><tr><td>1</td><td>Soft Reset</td></tr></table></div> <div>If this bit is not implemented, it must be ignored on write and read as zero. For Pre-Release 6, software should not write a 1 to this bit when its value is a 0, thereby causing a 0-to-1 transition. If such a transition is caused by software, it is UNPRE- DICTABLE whether hardware ignores or accepts the write. For Release 6, hardware ignores a write of 1.</div>	Encoding	Meaning	0	Not Soft Reset (NMI or Reset)	1	Soft Reset	R/W	1 for Soft Reset; 0 otherwise	Required if Soft Reset is implemented
Encoding	Meaning										
0	Not Soft Reset (NMI or Reset)										
1	Soft Reset

Encoding	Meaning										
0	Interrupts are disabled										
1	Interrupts are enabled										

1. The TS bit originally indicated a “TLB Shutdown” condition in which circuits detected multiple TLB matches and shutdown the TLB to prevent physical damage. In newer designs, multiple TLB matches do not cause physical damage to the TLB structure, so the TS bit retains its name, but is simply an indicator to the machine check exception handler that multiple TLB matches were detected and reported by the processor.

Programming Note:

In Release 2 of the Architecture, the EHB instruction can be used to make interrupt state changes visible when the *IM*, *IPL*, *ERL*, *EXL*, or *IE* fields of the *Status* register are written. See “Software Hazards and the Interrupt System” on page 96.

Table 9.50 indicates the relationship between $Status_{KX/SX/UX}$ in Release 5 and its effect on effective address generation for instruction and data addressing. “Special Behavior for Data References in User Mode with $Status_{UX} = 0$ ” on page 38 provides further detail.

Table 9.50 Release 5 Effective Address Generation

CP0 Status			Addressing in Kernel (K) / Supervisor (S) / User (U) Segments			
KX	SX	UX	Debug Mode ¹	Kernel Mode ²	Supervisor Mode ³	User Mode ^{4,5}
0	–	–	Canonical sign-extend	Canonical sign-extend	Canonical sign-extend	Canonical sign-extend
1	0	–	Unmodified 64-bit address	Unmodified 64-bit address	Canonical sign-extend	Canonical sign-extend
1	1	0	Unmodified 64-bit address	Unmodified 64-bit address	Unmodified 64-bit address	Canonical sign-extend
1	1	1	Unmodified 64-bit address	Unmodified 64-bit address	Unmodified 64-bit address	Unmodified 64-bit address

1. Processor is in debug mode if $Debug_{DM} = 1$.
2. Processor is in kernel mode if ($Debug_{DM} = 0$ and ($Status_{EXL} = 1$ or $Status_{ERL} = 1$ or $Status_{KSU} = 00$)).
3. Processor is in supervisor mode if ($Debug_{DM} = 0$ and $Status_{EXL} = 0$ and $Status_{ERL} = 0$ and $Status_{KSU} = 01$).
4. Processor is in user mode if ($Debug_{DM} = 0$ and $Status_{EXL} = 0$ and $Status_{ERL} = 0$ and $Status_{KSU} = 02$).
5. A kernel EVA memory access instruction operates as if in user mode.

9.34 IntCtl Register (CP0 Register 12, Select 1)

Compliance Level: *Required* (Release 2).

The *IntCtl* register controls the expanded interrupt capability added in Release 2 of the Architecture, including vectored interrupts and support for an external interrupt controller. This register does not exist in implementations of Release 1 of the Architecture.

Figure 9.36 shows the format of the *IntCtl* register; Table 9.51 describes the *IntCtl* register fields.

Figure 9.36 IntCtl Register Format

Table 9.52 SRSCtl Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
ESS	15..12	Exception Shadow Set. This field specifies the shadow set to use on entry to Kernel Mode caused by any exception other than a vectored interrupt. The operation of the processor is UNDEFINED if software writes a value into this field that is greater than the value in the HSS field.	R/W	0	Required
0	11..10	Must be written as zeros; returns zero on read.	0	0	Reserved
PSS	9..6	Previous Shadow Set. If GPR shadow registers are implemented, and with the exclusions noted in the next paragraph, this field is copied from the CSS field when an exception or interrupt occurs. An ERET instruction copies this value back into the CSS field if <i>Status_{BEV}</i> = 0. This field is not updated on any exception which sets <i>Status_{ERL}</i> to 1 (i.e., NMI or cache error), an entry into EJTAG Debug mode, or any exception or interrupt that occurs with <i>Status_{EXL}</i> = 1, or <i>Status_{BEV}</i> = 1. The operation of the processor is UNDEFINED if software writes a value into this field that is greater than the value in the HSS field.	R/W	0	Required
0	5..4	Must be written as zeros; returns zero on read.	0	0	Reserved
CSS	3..0	Current Shadow Set. If GPR shadow registers are implemented, this field is the number of the current GPR set. With the exclusions noted in the next paragraph, this field is updated with a new value on any interrupt or exception, and restored from the <i>PSS</i> field on an ERET. Table 9.53 describes the various sources from which the CSS field is updated on an exception or interrupt. This field is not updated on any exception which sets <i>Status_{ERL}</i> to 1 (i.e., NMI or cache error), an entry into EJTAG Debug mode, or any exception or interrupt that occurs with <i>Status_{EXL}</i> = 1, or <i>Status_{BEV}</i> = 1. Neither is it updated on an ERET with <i>Status_{ERL}</i> = 1 or <i>Status_{BEV}</i> = 1. The value of <i>CSS</i> can be changed directly by software only by writing the <i>PSS</i> field and executing an ERET instruction.	R	0	Required

Table 9.53 Sources for new SRSCtl_{CSS} on an Exception or Interrupt

Exception Type	Condition	SRSCtl _{CSS} Source	Comment
Exception	All	SRSCtl _{ESS}	
Non-Vectored Interrupt	Cause _{IV} = 0	SRSCtl _{ESS}	Treat as exception

Table 9.53 Sources for new SRSCtl_{CSS} on an Exception or Interrupt (Continued)

Exception Type	Condition	SRSCtl _{CSS} Source	Comment
Vectored Interrupt	Cause _{IV} = 1 and Config3 _{VEIC} = 0 and Config3 _{VInt} = 1	SRSSMap _{VectNum} ×4+3 . . VectNum×4	Source is internal map register
Vectored EIC Inter- rupt	Cause _{IV} = 1 and Config3 _{VEIC} = 1	SRSCtl _{EICSS}	Source is external interrupt controller.

Programming Note:

A software change to the PSS field creates an instruction hazard between the write of the *SRSCtl* register and the use of a RDPGPR or WRPGPR instruction. This hazard must be cleared with a JR.HB or JALR.HB instruction as described in [“Hazard Clearing Instructions and Events” on page 123](#). A hardware change to the PSS field as the result of interrupt or exception entry is automatically cleared for the execution of the first instruction in the interrupt or exception handler.

9.36 SRSMap Register (CP0 Register 12, Select 3)

Compliance Level: *Required* in Release 2 (and subsequent releases) of the Architecture if Additional Shadow Sets and Vectored Interrupt Mode are Implemented

The *SRSMap* register contains 8 4-bit fields that provide the mapping from an vector number to the shadow set number to use when servicing such an interrupt. The values from this register are not used for a non-interrupt exception, or a non-vectored interrupt ($Cause_{IV} = 0$ or $IntCtl_{VS} = 0$). In such cases, the shadow set number comes from $SRSCtl_{ESS}$.

If $SRSCtl_{HSS}$ is zero, the results of a software read or write of this register are **UNPREDICTABLE**.

The operation of the processor is **UNDEFINED** if a value is written to any field in this register that is greater than the value of $SRSCtl_{HSS}$.

The *SRSMap* register contains the shadow register set numbers for vector numbers 7..0. The same shadow set number can be established for multiple interrupt vectors, creating a many-to-one mapping from a vector to a single shadow register set number.

Figure 9.38 shows the format of the *SRSMap* register; Table 9.54 describes the *SRSMap* register fields.

Figure 9.38 SRSMap Register Format

31	28	27	24	23	20	19	16	15	12	11	8	7	4	3	0

SSV3	15..12	Shadow register set number for Vector Number 3	R/W	0	Required
SSV2	11..8	Shadow register set number for Vector Number 2	R/W	0	Required
SSV1	7..4	Shadow register set number for Vector Number 1	R/W	0	Required
SSV0	3..0	Shadow register set number for Vector Number 0	R/W	0	Required

9.37 Cause Register (CP0 Register 13, Select 0)

Compliance Level: *Required.*

The *Cause* register primarily describes the cause of the most recent exception. In addition, fields also control software interrupt requests and the vector through which interrupts are dispatched. With the exception of the *IP*_{1..0}, *DC*, *IV*, and *WP* fields, all fields in the *Cause* register are read-only. Release 2 of the Architecture added optional support for an External Interrupt Controller (EIC) interrupt mode, in which *IP*_{7..2} are interpreted as the Requested Interrupt Priority Level (*RIPL*).

Figure 9.39 shows the format of the *Cause* register; Table 9.55 describes the *Cause* register fields.

Figure 9.39 Cause Register Format

Table 9.55 Cause Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance									
Name	Bits													
RIPL	15..10	Requested Interrupt Priority Level. In implementations of Release 2 of the Architecture (and subsequent releases) in which EIC interrupt mode is enabled (<i>Config3_{VEIC}</i> = 1), this field is the encoded (0..63) value of the requested interrupt. A value of zero indicates that no interrupt is requested. If EIC interrupt mode is not enabled (<i>Config3_{VEIC}</i> = 0), these bits take on a different meaning and are interpreted as the IP7..IP2 bits, described above.	R	Undefined	Optional (Release 2 and EIC interrupt mode only)									
IP1..IP0	9..8	Controls the request for software interrupts: <table border="1"><thead><tr><th>Bit</th><th>Name</th><th>Meaning</th></tr></thead><tbody><tr><td>9</td><td>IP1</td><td>Request software interrupt 1</td></tr><tr><td>8</td><td>IP0</td><td>Request software interrupt 0</td></tr></tbody></table> An implementation of Release 2 of the Architecture (and subsequent releases) which also implements EIC interrupt mode exports these bits to the external interrupt controller for prioritization with other interrupt sources.	Bit	Name	Meaning	9	IP1	Request software interrupt 1	8	IP0	Request software interrupt 0	R/W	Undefined	Required
Bit	Name	Meaning												
9	IP1	Request software interrupt 1												
8	IP0	Request software interrupt 0												
ExcCode	6..2	Exception code - see Table 9.56	R	Undefined	Required									
0	25:24, 20..16, 7, 1..0	Must be written as zero; returns zero on read.	0	0	Reserved									

Table 9.56 Cause Register ExcCode Field

Exception Code Value		Mnemonic	Description
Decimal	Hexadecimal		
0	0x00	Int	Interrupt
1	0x01	Mod	TLB modification exception
2	0x02	TLBL	TLB exception (load or instruction fetch)
3	0x03	TLBS	TLB exception (store)
4	0x04	AdEL	Address error exception (load or instruction fetch)
5	0x05	AdES	Address error exception (store)
6	0x06	IBE	Bus error exception (instruction fetch)
7	0x07	DBE	Bus error exception (data reference: load or store)
8	0x08	Sys	Syscall exception
9	0x09	Bp	Breakpoint exception. If EJTAG is implemented and an SDBBP instruction is executed while the processor is running in EJTAG Debug Mode, this value is written to the Debug _{DExcCode} field to denote an SDBBP in Debug Mode.
10	0x0a	RI	Reserved instruction exception

Table 9.56 Cause Register ExcCode Field (Continued)

Exception Code Value		Mnemonic	Description
Decimal	Hexadecimal		
11	0x0b	CpU	Coprocessor Unusable exception
12	0x0c	Ov	Arithmetic Overflow exception
13	0x0d	Tr	Trap exception
14	0x0e	MSAFPE	MSA Floating-Point exception
15	0x0f	FPE	Floating-Point exception
16-17	0x10-0x11	-	Available for implementation-dependent use
18	0x12	C2E	Reserved for precise Coprocessor 2 exceptions
19	0x13	TLBRI	TLB Read-Inhibit exception
20	0x14	TLBXI	TLB Execution-Inhibit exception
21	0x15	MSADis	MSA Disabled exception
22	0x16	MDMX	Previously MDMX Unusable Exception (MDMX ASE). MDMX deprecated with Revision 5.
23	0x17	WATCH	Reference to WatchHi/WatchLo address
24	0x18	MCheck	Machine check
25	0x19	Thread	Thread Allocation, Deallocation, or Scheduling Exceptions (MIPS® MT Module)
26	0x1a	DSPDis	DSP Module State Disabled exception (MIPS® DSP Module)
27	0x1b	GE	Virtualized Guest Exception
28-29	0x1c - 0x1d	-	Reserved
30	0x1e	CacheErr	Cache error. In normal mode, a cache error exception has a dedicated vector and the Cause register is not updated. If EJTAG is implemented and a cache error occurs while in Debug Mode, this code is written to the Debug _{DExcCode} field to indicate that re-entry to Debug Mode was caused by a cache error.
31	0x1f	-	Reserved

Programming Note:

In Release 2 of the Architecture (and the subsequent releases), the EHB instruction can be used to make interrupt state changes visible when the IP_{1..0} field of the *Cause* register is written. See [“Software Hazards and the Interrupt System” on page 96](#).

9.38 NestedExc (CP0 Register 13, Select 5)

Compliance Level: *Optional*.

The *Nested Exception* (*NestedExc*) register is a read-only register containing the values of *Status_{EXL}* and *Status_{ERL}* prior to acceptance of the current exception.

This register is part of the Nested Fault feature, existence of the register can be determined by reading the *Config5_{NFExists}* bit.

Figure 9.40 shows the format of the *NestedExc* register; Table 9.57 describes the *NestedExc* register fields.

Figure 9.40 NestedExc Register Format

Table 9.57 NestedExc Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
0	31..3	Reserved, read as 0.	R0	0	Required
ERL	2	Value of <i>Status_{ERL}</i> prior to acceptance of current exception. Updated by all exceptions that would set either <i>Status_{EXL}</i> or <i>Status_{ERL}</i> . Not updated by Debug exceptions.	R	Undefined	Required
EXL	1	Value of <i>Status_{EXL}</i> prior to acceptance of current exception. Updated by exceptions which would update EPC if <i>Status_{EXL}</i> is not set (MCheck, Interrupt, Address Error, all TLB exceptions, Bus Error, CopUnusable, Reserved Instruction, Overflow, Trap, Syscall, FPU, etc.). For these exception types, this register field is updated regardless of the value of <i>Status_{EXL}</i> . Not updated by exception types which update <i>ErrorEPC</i> - (Reset, Soft Reset, NMI, Cache Error). Not updated by Debug exceptions.	R	Undefined	Required
0	0	Reserved, read as 0.	R0	0	Required

9.39 Exception Program Counter (CP0 Register 14, Select 0)

Compliance Level: *Required.*

The *Exception Program Counter (EPC)* is a read/write register that contains the address at which processing resumes after an exception has been serviced. All bits of the *EPC* register are significant and must be writable.

Unless the *EXL* bit in the *Status* register is already a 1, the processor writes the *EPC* register when an exception occurs.

- For synchronous (precise) exceptions, *EPC* contains either:
 - the virtual address of the instruction that was the direct cause of the exception, or
 - the virtual address of the immediately preceding branch or jump instruction, when the exception causing instruction is in a branch delay slot, and the *Branch Delay* bit in the *Cause* register is set.
- For asynchronous (imprecise) exceptions, *EPC* contains the address of the instruction at which to resume execution.

The processor reads the *EPC* register as the result of execution of the ERET instruction.

Software may write the *EPC* register to change the processor resume address and read the *EPC* register to determine at what address the processor will resume.

Figure 9.41 shows the format of the *EPC* register; Table 9.58 describes the *EPC* register fields.

Figure 9.41 EPC Register Format

Table 9.58 EPC Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
EPC	63..0	Exception Program Counter	R/W	Undefined	Required

9.39.1 Special Handling of the EPC Register in Processors that Implement MIPS16e ASE or microMIPS64 Base Architecture

In processors that implement the MIPS16e ASE or microMIPS64 base architecture, the *EPC* register requires special handling.

When the processor writes the *EPC* register, it combines the address at which processing resumes with the value of the *ISA Mode* register:

$$\text{EPC} \leftarrow \text{resumePC}_{63..1} \parallel \text{ISAMode}_0$$

“resumePC” is the address at which processing resumes, as described above.

When the processor reads the *EPC* register, it distributes the bits to the *PC* and *ISAMode* registers:

$$\begin{aligned} \text{PC} &\leftarrow \text{EPC}_{63..1} \parallel 0 \\ \text{ISAMode} &\leftarrow \text{EPC}_0 \end{aligned}$$

Software reads of the *EPC* register simply return to a GPR the last value written with no interpretation. Software writes to the *EPC* register store a new value which is interpreted by the processor as described above.

9.40 Nested Exception Program Counter (CP0 Register 14, Select 2)

Compliance Level: *Optional*.

The *Nested Exception Program Counter* (*NestedEPC*) is a read/write register with the same behavior as the *EPC* register except that:

- The *NestedEPC* register ignores the value of *Status_{EXL}* and is therefore updated on the occurrence of any exception, including nested exceptions.
- The *NestedEPC* register is not used by the ERET/DERET/IRET instructions. Software is required to copy the value of the *NestedEPC* register to the *EPC* register if it is desired to return to the address stored in *NestedEPC*.

This register is part of the Nested Fault feature, existence of the register can be determined by reading the *Config5_{NFExists}* bit.

Figure 9.42 shows the format of the *NestedEPC* register; Table 9.59 describes the *NestedEPC* register fields.

Figure 9.42 NestedEPC Register Format

0

Table 9.59 NestedEPC Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
NestedEPC	63..0	<p>Nested Exception Program Counter</p> <p>Updated by exceptions which would update EPC if <i>Status_{EXL}</i> is not set (MCheck, Interrupt, Address Error, all TLB exceptions, Bus Error, CopUnusable, Reserved Instruction, Overflow, Trap, Syscall, FPU, etc.). For these exception types, this register field is updated regardless of the value of <i>Status_{EXL}</i>.</p> <p>Not updated by exception types which update <i>ErrorEPC</i> - (Reset, Soft Reset, NMI, Cache Error).</p> <p>Not updated by Debug exceptions.</p>	R/W	Undefined	Required

9.41 Processor Identification (CP0 Register 15, Select 0)

Compliance Level: *Required.*

The *Processor Identification (PRId)* register is a 32 bit read-only register that contains information identifying the manufacturer, manufacturer options, processor identification and revision level of the processor. [Figure 9.43](#) shows the format of the *PRId* register; [Table 9.60](#) describes the *PRId* register fields.

Figure 9.43 PRId Register Format

31	24	23	16	15	8	7	0
Company Options		Company ID		Processor ID		Revision	

Table 9.60 PRId Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance								
Name	Bits												
Company Options	31..24	Available to the designer or manufacturer of the processor for company-dependent options. The value in this field is not specified by the architecture. If this field is not implemented, it must read as zero.	R	Preset by hardware	Optional								
Company ID	23..16	Identifies the company that designed or manufactured the processor. Software can distinguish a MIPS32/microMIPS32 or MIPS64/microMIPS64 processor from one implementing an earlier MIPS ISA by checking this field for zero. If it is non-zero the processor implements the MIPS32/microMIPS32 or MIPS64/microMIPS64 Architecture. Company IDs are assigned by MIPS Technologies when a MIPS32/microMIPS32 or MIPS64/microMIPS64 license is acquired. The encodings in this field are: <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>Not a MIPS32/microMIPS32 or MIPS64/microMIPS64 processor</td></tr><tr><td>1</td><td>MIPS Technologies, Inc.</td></tr><tr><td>2-255</td><td>Contact MIPS Technologies, Inc. for the list of Company ID assignments</td></tr></table>	Encoding	Meaning	0	Not a MIPS32/microMIPS32 or MIPS64/microMIPS64 processor	1	MIPS Technologies, Inc.	2-255	Contact MIPS Technologies, Inc. for the list of Company ID assignments	R	Preset by hardware	Required
Encoding	Meaning												
0	Not a MIPS32/microMIPS32 or MIPS64/microMIPS64 processor												
1	MIPS Technologies, Inc.												
2-255	Contact MIPS Technologies, Inc. for the list of Company ID assignments												
Processor ID	15..8	Identifies the type of processor. This field allows software to distinguish between various processor implementations within a single company, and is qualified by the CompanyID field, described above. The combination of the CompanyID and ProcessorID fields creates a unique number assigned to each processor implementation.	R	Preset by hardware	Required								
Revision	7..0	Specifies the revision number of the processor. This field allows software to distinguish between one revision and another of the same processor type. If this field is not implemented, it must read as zero.	R	Preset by hardware	Optional								

Software should not use the fields of this register to infer configuration information about the processor. Rather, the configuration registers should be used to determine the capabilities of the processor. Programmers who identify cases in which the configuration registers are not sufficient, requiring them to revert to check on the *PRId* register value, should send email to support@mips.com, reporting the specific case.

9.42 EBase Register (CP0 Register 15, Select 1)

Compliance Level: *Required* (Release 2).

The *EBase* register is a read/write register containing the base address of the exception vectors used when *Status_{BEV}* equals 0, and a read-only CPU number value that may be used by software to distinguish different processors in a multi-processor system.

The *EBase* register provides the ability for software to identify the specific processor within a multi-processor system, and allows the exception vectors for each processor to be different, especially in systems composed of heterogeneous processors. Bits 31..12 of the *EBase* register are concatenated with zeros to form the base of the exception vectors when *Status_{BEV}* is 0. The exception vector base address comes from the fixed defaults (see 6.2.2 “Exception Vector Locations” on page 98) when *Status_{BEV}* is 1, or for any EJTAG Debug exception. The reset state of bits 31..12 of the *EBase* register initialize the exception base register to 0xFFFF.FFFF.8000.0000, providing backward compatibility with Release 1 implementations.

If the write-gate bit is not implemented, bits 31..30 of the *EBase* register are fixed with the value 0b10, and the addition of the base address and the exception offset is done inhibiting a carry between bit 29 and bit 30 of the final exception address. The combination of these two restrictions forces the final exception address to be in the kseg0 or kseg1 unmapped virtual address segments. For cache error exceptions, bit 29 is forced to a 1 in the ultimate exception base address so that this exception always runs in the kseg1 unmapped, uncached virtual address segment.

The operation of the *EBase* register can be optionally extended to allow the upper bits of the Exception Base field to be written. This allows exception vectors to be placed anywhere in the address space. To ensure backward compatibility with MIPS64, the write-gate bit must be set before the upper bits can be changed. For the write-gate case, the full set of bits 63..12 are used to compute the vector location. Software can detect the existence of the write-gate by writing one to that bit position and checking if the bit was set.

The addition of the base address and the exception offset is performed inhibiting a carry between bits 29 and 30 of the final exception address.

If the value of the exception base register is to be changed, this must be done with *Status_{BEV}* equal 1. The operation of the processor is **UNDEFINED** if the Exception Base field is written with a different value when *Status_{BEV}* is 0.

Release 6 reuses the field CPUNum if multithreading is implemented.

Figure 9.44 shows the format of the *EBase* register if the write-gate is not implemented. ; Table 9.61 describes the *EBase* register fields.

Figure 9.44 EBase Register Format

31	30	29				12	11	10	9			0
1	0	Exception Base						0	0	CPUNum		

Table 9.61 EBase Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
1	31	This bit is ignored on write and returns one on read.	R	1	Required
0	30	This bit is ignored on write and returns zero on read.	R	0	Required
Exception Base	29..12	In conjunction with bits 31..30, this field specifies the base address of the exception vectors when <i>Status_{BEV}</i> is zero.	R/W	0	Required
0	11..10	Must be written as zero; returns zero on read.	0	0	Reserved
CPUNum	9..0	<p>This field specifies the number of the CPU in a multi-processor system and can be used by software to distinguish a particular processor from the others. The value in this field is set by inputs to the processor hardware when the processor is implemented in the system environment. In a single processor system, this value should be set to zero.</p> <p>This field can also be read through <i>RDHWR</i> register 0.</p> <p>In Release 6 of the architecture, with multi-threading supported, CPUNum is replaced by VPNum to indicate the virtual processor number. See Section 9.8, "Global Number Register (COP0 Register 3, Select 1)," for usage. In the absence of multi-threading, CPUNum can be used as defined.</p>	R	Preset by hardware or Externally Set	Required

[Figure 9.45](#) shows the format of the *EBase* register if the write-gate is implemented. [Table 9.62](#) describes the *EBase* register fields.

Figure 9.45 EBase Register Format

Table 9.62 EBase Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
Exception Base	63..12	<p>This field specifies the base address of the exception vectors when <i>Status_{BEV}</i> is zero.</p> <p>Bits 63..30 can be written only when WG is set. When WG is zero, these bits are unchanged on write.</p>	R/W	0xFFFFFFFF FF80000	Required
WG	11	Write gate. Bits 63..30 are unchanged on writes to EBase when WG=0 in the value being written. The WG bit must be set true in the written value to change the values of bits 63..30.	R/W	0	Required

Table 9.62 EBase Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
0	10	Must be written as zero; returns zero on read.	R0	0	Reserved
CPUNum	9..0	<p>This field specifies the number of the CPU in a multi-processor system and can be used by software to distinguish a particular processor from the others. The value in this field is set by inputs to the processor hardware when the processor is implemented in the system environment. In a single processor system, this value should be set to zero.</p> <p>This field can also be read via RDHWR register 0.</p> <p>In Release 6 of the architecture, with multi-threading supported, CPUNum is replaced by VPNum to indicate the virtual processor number. See Section 9.8, "Global Number Register (COP0 Register 3, Select 1)," for usage. In the absence of multi-threading, CPUNum can be used as defined.</p>	R	Preset or Externally Set	Required

Programming Note:

Software must set EBase_{15..12} to zero in all bit positions less than or equal to the most-significant bit in the vector offset. This situation can only occur when a vector offset greater than 0xFFF is generated when an interrupt occurs with *VI* or *EIC* interrupt mode enabled. The operation of the processor is **UNDEFINED** if this condition is not met. [Table 9.63](#) shows the conditions under which each *EBase* bit must be set to zero. *VN* represents the interrupt vector number as described in [Table 6.4](#) and the bit must be set to zero if any of the relationships in the row are true. No *EBase* bits must be set to zero if the interrupt vector spacing is 32 (or zero) bytes.

Table 9.63 Conditions Under Which EBase_{15..12} Must Be Zero

EBase bit	Interrupt Vector Spacing in Bytes (IntCtl _{VS} ¹)				
	32	64	128	256	512
15	None	None	None	None	VN ≥ 63
14		None	None	VN ≥ 62	VN ≥ 31
13		None	VN ≥ 60	VN ≥ 30	VN ≥ 15
12		VN ≥ 56	VN ≥ 28	VN ≥ 14	VN ≥ 7

1. See [Table 9.51 on page 225](#)

9.43 CDMMBase Register (CP0 Register 15, Select 2)

Compliance Level: *Optional*.

The 64-bit physical base address for the Common Device Memory Map facility is defined by this register. This register only exists if *Config3_{CDMM}* is set to one.

For devices that implement multiple VPEs, access to this register is controlled by the *VPEConf0_{MVP}* register field. If the *MVP* bit is cleared, a read to this register returns all zeros and a write to this register is ignored.

Figure 9.46 has the format of the *CDMMBase* register, and Table 9.64 describes the register fields.

Figure 9.46 CDMMBase Register

63	60	59				11	10	9	8		0
0	CDMM_UPPER_ADDR						EN	CI	CDMMSize		

Table 9.64 CDMMBase Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance						
Name	Bits										
0	63:60	Must be written as zero; returns zero on read	0	0	Reserved						
CDMM_UP PER_ADDR	59:11	Bits 63:15 of the base physical address of the memory mapped registers. The number of implemented physical address bits is implementation specific, see Section “Physical Memory” on page 27. For the unimplemented address bits - writes are ignored, returns zero on read.	R/W	Undefined	Required						
EN	10	Enables the CDMM region. If this bit is cleared, memory requests to this address region go to regular system memory. If this bit is set, memory requests to this region go to the CDMM logic <table border="1"><thead><tr><th>Encoding</th><th>Meaning</th></tr></thead><tbody><tr><td>0</td><td>CDMM Region is disabled.</td></tr><tr><td>1</td><td>CDMM Region is enabled.</td></tr></tbody></table>	Encoding	Meaning	0	CDMM Region is disabled.	1	CDMM Region is enabled.	R/W	0	Required
Encoding	Meaning										
0	CDMM Region is disabled.										
1	CDMM Region is enabled.										
CI	9	If set to 1, this indicates that the first 64-byte Device Register Block of the CDMM is reserved for additional registers which manage CDMM region behavior and are not IO device registers.	R	Preset	Optional						

Table 9.64 CDMMBase Register Field Descriptions (Continued)

		2				3 DRBs											
												
511	512 DRBs																

9.44 CMGCRBase Register (CP0 Register 15, Select 3)

Compliance Level: *Optional*.

The 64-bit physical base address for the memory-mapped Coherency Manager Global Configuration Register space is reflected by this register. This register only exists if *Config3_{CMGCR}* is set to one.

On devices that implement the MIPS MT Module, this register is instantiated once per processor.

Figure 9.47 has the format of the *CMGCRBase* register, and Table 9.65 describes the register fields.

Figure 9.47 CMGCRBase Register

63	60	59		11	10		0
0	CMGCR_BASE_ADDR					0	

Table 9.65 CMGCRBase Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
CMGCR_BASE_ADDR	59:11	<p>Bits 63:15 of the base physical address of the memory-mapped Coherency Manager GCR registers.</p> <p>This register field reflects the value of the GCR_BASE field within the memory-mapped Coherency Manager GCR Base Register.</p> <p>The number of implemented physical address bits is implementation specific, see Section “Physical Memory” on page 27. For the unimplemented address bits - writes are ignored, returns zero on read.</p>	R	Preset by hardware (IP Configuration Value)	Required
0	63:60, 10:0	Must be written as zero; returns zero on read	0	0	Reserved

9.45 BEVVA Register (CP0 Register 15, Select 4)

Compliance Level: *Required.* if Release 5 Enhanced Virtual Addressing is supported (i.e., $Config5_{EVA}=1$).

The *BEVVA* register is a read-only register that captures the virtual address used to specify the Boot Exception Vector when it is programmable as required to support Release 5 Enhanced Virtual Addressing (EVA). In addition, it can be used to determine the size of the BEV Overlay which overlaps with BEV. The BEV Overlay is a configurable virtual address range that overlays kernel unmapped segment(s) in order to map to a configurable physical address.

The purpose of this register is to provide software visibility into BEV since the address is pin configurable i.e., not settable through COP0. It is optional for an implementation to allow programmability of the pins through a memory-mapped register external to the core, otherwise the pins may be hardwired to a non-legacy value.

For a 32-bit implementation that supports both legacy and EVA address maps, it is required to support two configurable overlays, for unmapped cached and uncached addresses. For an implementation that supports only EVA, one overlay is sufficient to map a virtual address within the range of the overlay to an implementation-dependent physical address. Where two are supported, the implementation must guarantee BEVVA corresponds to the single overlay that is in effect in EVA mode, as software requires a means to read the programmable BEV.

For 64-bit implementations, this register is supported only if the implementation supports 32-bit backward compatibility for EVA i.e., $Config5_{EVA}=1$. BEV in this case is sign-extended from its 32-bit value, locating it in one of two compatibility regions.

Figure 9.48 shows the format of the *BEVVA* register; Table 9.66 describes the *BEVVA* register fields.

Figure 9.48 BEVVA Register Format

Table 9.66 BEVVA Register Field Descriptions

Fields		Description	Read/ Write	Reset State	Compliance
Name	Bits				
Base	31..12	Boot Exception Vector (BEV) Virtual Address The BEV address is aligned on a 4KB boundary within the BEV overlay which is a minimum of 1MB and maximum of 256MB in size.	R	Externally set or Preset by hardware	Required
0	11:8	0	0	0	Reserved

Table 9.66 BEVVA Register Field Descriptions

Fields		Description	Read/ Write	Reset State	Compliance
Name	Bits				
Mask	7:0	<p>Mask to define the size of the overlay.</p> <p>Applies to bits 27:20 of <i>Base</i>, that is, $BEV_Overlay[31:20] = BEVVA[31:20] \& (0xf \parallel \sim Mask)$</p> <p><i>Mask</i> is encoded as follows to define size of overlay:</p> <p>8'b00000000 - 1 MB 8'b00000001 - 2 MB 8'b00000011 - 4 MB 8'b00000111 - 8 MB 8'b00001111 - 16 MB 8'b00011111 - 32 MB 8'b00111111 - 64 MB 8'b01111111 - 128 MB 8'b11111111 - 256MB</p> <p>An encoding other than that shown above is not supported and causes UNDEFINED results.</p>	R	Externally set or Preset by hardware	Required

9.46 Configuration Register (CP0 Register 16, Select 0)

Compliance Level: *Required.*

The *Config* register specifies various configuration and capabilities information. Most of the fields in the *Config* register are initialized by hardware during the Reset Exception process, or are constant. Three fields, *K23*, *KU*, and *K0*, must be initialized by software in the reset exception handler.

Figure 9.49 shows the format of the *Config* register; Table 9.67 describes the *Config* register fields.

Figure 9.49 Config Register Format

9.47 Configuration Register 1 (CP0 Register 16, Select 1)

Compliance Level: *Required.*

The *Config1* register is an adjunct to the *Config* register and encodes additional capabilities information. All fields in the *Config1* register are read-only.

The I-Cache and D-Cache configuration parameters include encodings for the number of sets per way, the line size, and the associativity. The total cache size for a cache is therefore:

$$\text{Cache Size} = \text{Associativity} * \text{Line Size} * \text{Sets Per Way}$$

If the line size is zero, there is no cache implemented.

Figure 9.50 shows the format of the *Config1* register; Table 9.68 describes the *Config1* register fields.

Figure 9.50 Config1 Register Format

9.48 Configuration Register 2 (CP0 Register 16, Select 2)

Compliance Level: *Required* if a level 2 or level 3 cache is implemented, or if the *Config3* register is required; *Optional* otherwise. In Release 6, presence of *Config2* is dependent on *Config5_{L2C}*.

The *Config2* register encodes level 2 and level 3 cache configurations.

Figure 9.51 shows the format of the *Config2* register; Table 9.69 describes the *Config2* register fields.

0	Trace logic is not implemented										
1	Trace logic is implemented										

9.50 Configuration Register 4 (CP0 Register 16, Select 4)

Compliance Level: *Required* if any optional feature described by this register is implemented: Release 2 of the Architecture; *Optional* otherwise.

The *Config4* register encodes additional capabilities.

The number of page-pair entries within the FTLB = decode(FTLBSets) * decode(FTLBWays).

The number of page-pair entries accessible in the VTLB is defined by concatenating *Config4*_{VTLBSizeExt} and *Config1*_{MMUSize}. Modifying VTLB size can be used to allow software to reserve high index slots in the VTLB.

Figure 9.54 shows the format of the *Config4* register; Table 9.71 describes the *Config4* register fields.

Figure 9.53 Config4 Register Format (Pre-Release 6)

31	30	29	28	27	24	23	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

		5				1 GB																	
		6				4 GB																	
7	Reserved																						
Implementations are allowed to implement any subset of these sizes, even a subset of only one pagesize. Software can detect if a FTLB page size is implemented by writing the desired size into this register field. If the size is implemented, the register field is updated to the desired encoding. If the size is not implemented, the register field value is not changed.																							
The FTLB must be flushed of any valid entries before this register field value is changed by software. The FTLB behavior is UNDEFINED if there are valid FTLB entries which were not all programmed using a common page size.

R	Preset by hardware	Required if $MMU_{ExtDef}=1$ (Pre-Release 6)																																		

9.51 Configuration Register 5 (CP0 Register 16, Select 5)

Compliance Level: *Required* if any optional feature described by this register is implemented: Release 3 of the Architecture; *Optional* otherwise.

The Config5 register encodes additional capabilities:

- Cache Error exception vector control.
- Segmentation Control legacy compatibility.
- Existence of EVA instructions (for example, LBE).
- Existence of the User Mode FP Register mode-changing facility (*UFR*).
- Existence of the Nested Fault feature (*NestedExc*, *NestedEPC*).
- Existence of COP0 *MAAR* and *MAARI* (*MRP*).
- Support for additional LL/SC instruction handling capabilities (*LLB*).
- Existence of MTHC0 and MFHC0 instructions (*MHV*).
- Kernel control over non-kernel execution of SDBBP (*SBRI*).
- Existence of Config2 (L2 and L3 cache configurations) in COP0 (*L2C*).
- Support for COP0 capabilities related to multi-threading (*VP*).
- Support for trap and emulate capability for floating-point (*FRE/UFE*).
- Support for software reset-based Endian switching (*DEC*).
- Determine presence of Release 6 LLX/SCX family of instructions (*XNP*).

Figure 9.55 shows the format of the *Config5* register; Table 9.72 describes the *Config5* register fields.

1	Additional support exists: <ul style="list-style-type: none">• ERETNC instruction added.• CP0 <i>LLAddr_{LLB}</i> is mandatory.• <i>LLbit</i> is software accessible through <i>LLAddr</i>[0].• SC instruction behavior is modified.									
MRP	3	COP0 Memory Accessibility Attribute Registers, <i>MAAR</i> and <i>MAARI</i> , are present.	R	Preset by hardware	Required if MAAR(I) implemented (Release 5)					
		Encoding	Meaning	0	<i>MAAR</i> and <i>MAARI</i> not present.	1	<i>MAAR</i> and <i>MAARI</i> present. Software may program these registers to apply additional attributes to fetch/load/store access to memory/IO address ranges.			
		Encoding	Meaning							
0	<i>MAAR</i> and <i>MAARI</i> not present.									
1	<i>MAAR</i> and <i>MAARI</i> present. Software may program these registers to apply additional attributes to fetch/load/store access to memory/IO address ranges.									
UFR	2	This feature allows user-mode access to <i>Status_{FR}</i> using CTC1 and CFC1 instructions.	R/W if <i>FIR_{UFRP}</i> = 1 else 0 ²	0	Optional in (Release 5)					
		Encoding	Meaning	0	User-mode FR instructions not allowed.	1	User-mode FR instructions allowed.	R	0	Reserved (Release 6)
		Encoding	Meaning							
0	User-mode FR instructions not allowed.									
1	User-mode FR instructions allowed.									
NF Exists	0	Indicates that the Nested Fault feature exists. The Nested Fault feature allows recognition of faulting behavior within an exception handler.	R	Preset	Required if the Nested Fault feature exists.					

1. Note on *Config5_K*, Segment CCA determination: [Table 9.72](#) below shows which field determines the CCA of a segment when *Config5_K*=0 or *Config5_K*=1, on implementations with/without a TLB, when the region is accessed unmapped.
2. *Config5_{UFR}* is R/W if an FPU is present, and if the User-mode FR changing feature is present, i.e. if *FIR_{UFRP}* is set. Otherwise *Config5_{UFR}* is 0.

Table 9.73 SegCtl0_K Segment CCA Determination

Segment	Config5 _K =0	Config5 _K =0	Config5 _K =1
	No TLB	With TLB	
0	<i>Config_{K23}</i>	Undefined ¹	<i>SegCtl0_{C0}</i>
1	<i>Config_{K23}</i>	Undefined ¹	<i>SegCtl0_{C1}</i>
2	<i>SegCtl1_{C2}</i>	<i>SegCtl1_{C2}</i>	<i>SegCtl1_{C2}</i>
3	<i>Config_{K0}</i>	<i>Config_{K0}</i>	<i>SegCtl1_{C3}</i>
4	<i>Config_{KU}</i>	Undefined ¹	<i>SegCtl2_{C4}</i>
5	<i>Config_{KU}</i>	Undefined ¹	<i>SegCtl2_{C5}</i>

1. Note: Reset state of these regions is mapped on implementations containing a TLB. Software must set *Config5_K*=1 if it is programming any of these segments to be used as unmapped on an implementation containing a TLB.

9.52 Reserved for Implementations (CP0 Register 16, Selects 6 and 7)

Compliance Level: *Implementation Dependent.*

CP0 register 16, Selects 6 and 7 are reserved for implementation-dependent use and is not defined by the architecture. In order to use CP0 register 16, Selects 6 and 7, it is not necessary to implement CP0 register 16, Selects 2 through 5 only to set the *M* bit in each of these registers. That is, if the *Config2* and *Config3* registers are not needed for the implementation, they need not be implemented just to provide the M bits.

The architecture only defines the use of the M bits for presence detection of Selects 1 to 5.

9.53 Load Linked Address (CP0 Register 17, Select 0)

Compliance Level: *Optional* prior to Release 5. *Required* in Release 5 if *Config5_{LLB}*=1. *Required* in Release 6.

The *LLAddr* register contains relevant bits of the physical address read by the most recent Load Linked instruction. This register is implementation-dependent, is for diagnostic purposes only, and serves no function during normal operation.

Release 5 also provides software with the ability to read and clear the LLbit, which is set when an LL instruction is executed. The presence of LLB in *LLAddr* in Release 5 can be detected by software through *Config5_{LLB}*.

In Release 6, *Config5_{LLB}* is read-only 1, and CP0 *LLAddr* is required.

Figure 9-56 shows the format of the *LLAddr* register and Table 9.74 describes the *LLAddr* register fields for pre-Release 5 implementations.

Figure 9-57 shows the format of the *LLAddr* register; Table 9.75 describes the *LLAddr* register fields.

Figure 9-56 LLAddr Register Format (pre Release 5)

Table 9.74 LLAddr Register Field Descriptions (pre Release 5)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
PAddr	63..0	This field encodes the physical address read by the most recent Load Linked instruction. The format of this register is implementation-dependent, and an implementation may implement as many of the bits or format the address in any way that it finds convenient.	R	Undefined	Optional

Figure 9-57 LLAddr Register Format (Release 5 and after)

Table 9.75 LLAddr Register Field Descriptions (Release 5 and after)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
PAddr	63..1	<p>This field encodes the physical address read by the most recent Load Linked instruction. The format of this register is implementation-dependent, and an implementation may implement as many of the bits or format the address in any way that it finds convenient.</p> <p><i>LLAddr</i>[1] is always aligned to PA[5], which implies that <i>PAddr</i> is always 32-byte aligned.</p> <p>The number of physical address bits is implementation-specific. For the unimplemented address bits, writes are ignored and reads return zero.</p>	R	Undefined	<p>Optional (Release 5)</p> <p>Required (Release 6)</p>
LLB	0	<p>LLbit.</p> <p><i>LLB</i> is set when the LLD instruction is executed. The SC instructions and other hardware events may clear <i>LLB</i>. This field allows the LLbit to be software accessible. <i>LLB</i> can be cleared by software but cannot be set.</p>	R/W	0	<p>Required if <i>Config5_{LLB}</i>=1 (Release 5)</p> <p>Required (Release 6)</p>

9.54 Memory Accessibility Attribute Register (CP0 Register 17, Select 1)

Compliance Level: *Optional*

The *MAAR* register is a read/write register included in Release 5 of the architecture that defines the accessibility attributes of physical address regions. In particular, *MAAR* defines whether a instruction fetch or data load can speculatively access such a region within the physical address bounds specified by the *MAAR*.

If the *MAAR* function yields a valid attribute, it will only override any equivalent attribute determined through other means, if it provides a more conservative outcome. For example, if the MMU yields a cacheable CCA, but *MAAR* yields a speculate attribute set to 0, then the access should not speculate as determined by the *MAAR* result. Similarly, if the MMU yields an uncacheable CCA, but *MAAR* yields a speculate attribute set to 1, then the access should not speculate.

In Release 5, the CCA of an access now defines whether the access can speculate, along with *MAAR*. An access with a cacheable CCA is allowed to speculate. An access with uncacheable CCA on the other hand is not allowed to speculate unless the uncacheable CCA=7 (UCA) is used. The final speculative attribute is a combination of the CCA and *MAAR* as described above.

The address range specified by a *MAAR* may be used to specify an attribute for any region of the address space, whether memory (DRAM) or memory-mapped I/O.

The definition of *MAAR* is impacted by Extended Physical Addressing (XPA), a MIPS32 Release 5 feature. In a 32-bit implementation, if XPA is supported, then *MAAR* must be extended by additional physical address bits. To maintain atomicity of the write to an extended *MAAR*, two valid bits, VL and VH are required. The presence and use of both bits is conditional on *PageGrain_{ELPA}* and *Config5_{MVH}*.

Both VL and VH will be present if *Config5_{MVH}*=1. In this circumstance, VH is effective if *PageGrain_{ELPA}*=1, otherwise it is reserved. When effective, 32-bit software must use MTHC0 to write this bit. 64-bit software must use DMTCH0, though 32-bit software running on a 64-bit implementation will use MTHC0.

It is recommended that Release 5 implementations of the architecture include the *MAAR* feature to allow architectural instead of implementation-dependent definition of speculation.

The Release 5 specification of *MAAR* requires that *MAAR* registers be paired, i.e., one specifies an upper bounds of the address range, and the other the lower bound.

MAAR must be implemented in conjunction with *MAARI* (*MAAR Index*, CP0 Register 17, Sel 2). *MAARI* must be initialized with the appropriate *MAAR* register number before the *MAAR* is accessed with a COP0 move-to or move-from instruction. An EHB instruction is required to be placed between the write to *MAARI* and subsequent execution of the COP0 read or write that specifies *MAAR*.

The presence of *MAAR* can be detected by software through *Config5_{MRP}*.

Figure 9.58 and Figure 9.59 show the format of the *MAAR* register; Figure 9.59 and Figure 9.60 show the format of the *MAARI* register; Table 9.76 describes the *MAAR* register fields.

Operation:

The pseudo-code shows a 3-pair *MAAR* implementation to determine speculation. It is strongly recommended that implementations follow this description to enable portable software. As described, software must set the logical valid to 1 of each register in the pair to enable a *MAAR* pair, where the valid of each register may be composed of up to

two valids, a high and low. The logical valid is determined as given in [Table 9.77](#). Software may clear the logical valid of any one of the pair to invalidate the whole MAAR pair. Once the address range is valid, hardware factors in the speculate attribute of only the upper MAAR register with even index, as shown in [Table 9.78](#).

```
speculateCCA ← 0 // default is not to speculate
// Modify speculate attribute as per CCA of memory access (Release 5)
// Release 5: cached CCA and UCA speculates
if ((CCA == "cached") or (CCA == "uncached-accelerated(UCA)"))
    speculateCCA ← 1
endif

// Now factor in MAAR
MAARmatch ← 0
speculateMAAR ← 1
// Example of 40-bit PA is 64KB aligned; PA size is implementation-dependent.
PA_Align ← PA[39:16]
for (i=0; i<6; i=i+2) // assume 3 pairs
    // Factor in valid(s)
    MAAR[i]V = MAAR[i]VL and (MAAR[i]VH or not PageGrainELPA or not Config5MVH)
    MAAR[i+1]V = MAAR[i+1]VL and (MAAR[i+1]VH or not PageGrainELPA or not Config5MVH)
    if (MAAR[i]V and MAAR[i+1]V) // valids of both registers must be set to 1
        if ((MAAR[i][35:12] >= PA_Align) && // upper bound ; 40-bit PA.
            (MAAR[i+1][35:12] <= PA_Align)) // lower bound ; 40-bit PA.
            speculateMAAR ← speculateMAAR and MAAR[i]S
            MAARmatch ← 1
        endif
    endif
endifor

// if no MAAR is valid, or no MAAR match occurs, then speculateMAAR ← 0
speculate ← speculateMAAR and speculateCCA and MAARmatch
```

Programming Notes :

The purpose of *MAAR* is to control speculation on load or fetch access to memory and IO address. A fetch or load is considered speculative if it accesses memory prior to its being the oldest instruction to retire. For implementations that support load or fetch speculation, support and initialization of *MAAR* is a requirement.

MAAR as defined has the following properties :

- If all *MAAR* instances are invalid, then no speculation is allowed. (The state of *MAAR* is set to disallow speculation on reset.) This allows the *MAAR* initialization to occur at any point of time without the risk of execution speculative (mispredicted branch path) loads or fetches from issuing to IO addresses, with the tradeoff possibly being lower performance.
- If any *MAAR* region enables speculation, then accesses to physical addresses outside this *MAAR* region must be non-speculative, unless the physical address of the access matches against a *MAAR* region with speculation enabled. This access can then speculate.
- *MAAR* overlap is allowed : This allows non-speculative *MAAR* region to overlap a speculative *MAAR* region. For e.g., with this property, a non-speculative region can be overlaid on a speculative DRAM region with the use of just two *MAAR* pairs. If hardware supports such overlays, then the resultant speculate attribute of each region that overlaps must be logically and'ed.

Software must follow the described method for *reprogramming* the attribute state of a *MAAR* pair.

- Disable the *MAAR* pair by clearing *MAAR_{VL}*. Accesses to the *MAAR* region become non-speculative.
- Program *PageGrain_{ELPA}* as needed.
- Set *MAAR_{VL}* along with other fields in *MAAR*. 32-bit software uses *MTC0*, which initializes the lower half of *MAAR*. 64-bit software uses *DMTC0* to initialize the entire *MAAR*.
- Initialize *MAAR*[63:32], which is present if *PageGrain_{ELPA}*=1. This includes *MAAR_{VH}*, if *Config5_{MVH}*=1.

Figure 9.58 shows the format of *MAAR* when *PageGrain_{ELPA}*=0 i.e., *MAAR* is limited to a 32-bit register.

Figure 9.58 MAAR Register Format if PageGrain_{ELPA}=0

Figure 9-59 shows the format of *MAAR* when *PageGrain_{ELPA}*=1 and *Config5_{MVH}*=0 i.e., *MAAR* is a 64-bit register accessible only by *DMTC0* and *DMFC0*, and thus the upper valid bit is not present.

Figure 9-59 MAAR Register Format if PageGrain_{ELPA}=1 and Config5_{MVH}=0

Figure 9-60 shows the format of *MAAR* when *PageGrain_{ELPA}*=1 and *Config5_{MVH}* =1 i.e., *MAAR* is a 64-bit register accessible not only by *DMTC0* and *DMFC0*, but *MTHC0* and *MFHC0*, for 32-bit backward compatibility, and thus the upper valid bit is present.

Figure 9-60 MAAR Register Format if PageGrain_{ELPA}=1 and Config5_{MVH}=1

Table 9.76 MAAR Register Field Descriptions

Fields		Description	Read/Wri te	Reset State	Compliance						
Name	Bits										
VH	63	<p>Valid, High 32-bits VH is R0 if $Config5_{MVH}=0$. VH is R/W if $Config5_{MVH}=1$. VH only factors into any logic if it is R/W. If $PageGrain_{ELPA}=0$ when $Config5_{MVH}=1$ then MTC0 writes also clear VH. An MTHC0, if supported, may set or clear VH. An MTC0 always clears VH. For the case where $Config5_{MVH}=1$ but $PageGrain_{ELPA}=0$, software must always clear VH by writing $MAAR_{VH}$. DMTC0 will set VH if VL in write-data is 1, providing $Config5_{MVH}=1$. Otherwise, write to VH is ignored, VH is R0 and is not factored into logic. Prior to clearing $PageGrain_{ELPA}$, software must also clear $MAAR_{VH}$, if supported. Otherwise the upper half of MAAR is still effective in determining a MAAR match, which may yield an invalid result. <i>This is considered a programming error.</i></p> <p>If VH is R/W, then it is interpreted as follows : .</p> <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>MAAR[63:32] is not valid and thus this MAAR register should not modify the behavior of any instruction fetch or data load.</td></tr><tr><td>1</td><td>MAAR[63:32] is valid and thus this MAAR register may modify the behavior of any instruction fetch or data load.</td></tr></table> <p>See definition of VL also. If VH is present, then VL is truly considered 1 if VH is also 1. If $Config_{MVH}=1$, then both VL and VH must be factored into determining whether a MAAR register is valid : $MAAR_V = MAAR_{VL}$ and ($MAAR_{VH}$ or not $PageGrain_{ELPA}$ or not $Config5_{MVH}$) If $Config_{MVH}=0$ or $PageGrain_{ELPA}=0$, then this equation reduces to : $MAAR_V = MAAR_{VL}$ If both valids are present, and if either valid bit (as calculated above) of the MAAR register is set to 0, then the register is assumed invalid and thus will not modify behavior of a memory access. Software may thus clear one valid in one register of the MAAR pair to invalidate the MAAR comparison. It is recommended that only VL be cleared for software consistency with implementations that do not support VH.</p>	Encoding	Meaning	0	MAAR[63:32] is not valid and thus this MAAR register should not modify the behavior of any instruction fetch or data load.	1	MAAR[63:32] is valid and thus this MAAR register may modify the behavior of any instruction fetch or data load.	R/W, R0	0	Required or Reserved
Encoding	Meaning										
0	MAAR[63:32] is not valid and thus this MAAR register should not modify the behavior of any instruction fetch or data load.										
1	MAAR[63:32] is valid and thus this MAAR register may modify the behavior of any instruction fetch or data load.										

Table 9.76 MAAR Register Field Descriptions

Fields		Description	Read/Wri te	Reset State	Compliance						
Name	Bits										
0	62:56	Reserved. Writes are ignored, read as 0.	R	0	Required						
ADDR	55:12	Address bounds. ADDR must always specify a physical address. MAAR regions are 64KB aligned, and thus the least significant bit of ADDR is equal to PA[16]. If the register specifies the upper bound then any sourced address must be less than or equal to ADDR. If the register specifies the lower bound then any sourced address must be greater than or equal to ADDR. See MAAR Index (CP0 Register 17, Select 2) for method to determine which register is upper or lower in a pair. MAAR[12] = PA[16]. This allows a 32-bit MAAR to specify 36-bits of PA, where MAAR[31] = PA[35]. If $PageGrain_{ELPA} = 1$, then ADDR may be extended to a maximum of 59 physical address bits. Unused leading PA bits must be treated as reserved. For this purpose, the MAAR register must be extended by up to an additional 32-bits, accessible by MTHC0 and MFHC0 in MIPS32, which are defined in MIPS32 Release 5, or MIPS64 DMTC0 and DMFC0.	R/W	Undefined	Required						
0	15:2	Reserved. Writes are ignored, read as 0.	R	0	Required						
S	1	Speculate. If an access is qualified as non-speculative, it must be oldest in machine before being allowed to access memory or memory-mapped regions. <table border="1"><thead><tr><th>Encoding</th><th>Meaning</th></tr></thead><tbody><tr><td>0</td><td>Instruction fetch or data load that matches MAAR register pair address range is <i>never</i> allowed to speculatively access address range.</td></tr><tr><td>1</td><td>Instruction fetch or data load that matches MAAR register pair address range <i>may</i> be allowed to speculate.</td></tr></tbody></table> MAAR regions are allowed to overlap. The cumulative speculative attribute for overlapping regions is determined by ANDing individual valid MAAR pair speculation attributes.	Encoding	Meaning	0	Instruction fetch or data load that matches MAAR register pair address range is <i>never</i> allowed to speculatively access address range.	1	Instruction fetch or data load that matches MAAR register pair address range <i>may</i> be allowed to speculate.	R/W	Undefined	Required
Encoding	Meaning										
0	Instruction fetch or data load that matches MAAR register pair address range is <i>never</i> allowed to speculatively access address range.										
1	Instruction fetch or data load that matches MAAR register pair address range <i>may</i> be allowed to speculate.

R/W	0	Required
Encoding	Meaning										
0	MAAR[31:0] is not valid and should not modify behavior of any instruction fetch or data load.										
1	MAAR[31:0] is valid and <i>may</i> modify behavior of any instruction fetch or data load that falls within the range of addresses specified by the MAAR register pair.										

Table 9.77 shows how the valid attribute for a *MAAR* pair is determined from the cumulative individual *MAAR* register valids.

Table 9.77 Valid Determination for MAAR Pair

MAAR[i] _v where i is even	MAAR[i+1] _v	Resultant Valid
0	0	Result is invalid
0	1	Result is invalid
1	0	Result is invalid
1	1	Result is valid

Table 9.78 shows how the speculate attribute for a *MAAR* pair is determined by the cumulative individual speculate attributes.

Table 9.78 Speculate Determination for MAAR Pair

MAAR[i] _s where i is even	MAAR[i+1] _s	Result
1	0/1	Valid access may speculate
0	0/1	Valid access may never speculate

9.55 Memory Accessibility Attribute Register Index (CP0 Register 17, Select 2)

Compliance Level: *Optional* (Release 5)

MAAR Index is used in conjunction with an implementation that supports *MAAR* registers (CP0 Register 17, Select 1). Multiple *MAAR* registers may be implemented - *MAAR Index* is used to specify a *MAAR* register number that may be accessed by software with an MTC0 or MFC0 instruction.

MAAR Index is always required if *MAAR* (CP0 Register 17, Select 1) is supported. This is because *MAAR* registers are paired in Release 5, and thus there is always more than one *MAAR* register.

Prior to access by MTC0 or MFC0, software must set *MAARI_{INDEX}* to the appropriate value.

Figure 9.61 shows the format of the *MAAR Index* register; Table 9.79 describes the *MAAR Index* register fields.

The presence of *MAARI* can be detected by software through *Config5_{MRP}*.

Figure 9.61 MAARI Index Register Format

Table 9.79 MAARI Index Register Field Descriptions

Fields		Description	Read/Write	Reset State	Compliance						
Name	Bits										
0	31:6	Reserved. Writes are ignored, read as 0.	R	0	Required						
INDEX	5:0	<p>MAAR Index</p> <p>The number of <i>MAAR</i> registers is greater than 1. <i>INDEX</i> specifies the <i>MAAR</i> register to access.</p> <p>MAAR registers are paired. The least-significant bit of <i>INDEX</i> is encoded as follows to indicate which register of the pair is being accessed.</p> <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>This register specifies the upper address bound of the <i>MAAR</i> register pair.</td></tr><tr><td>1</td><td>This register specifies the lower address bound of the <i>MAAR</i> register pair.</td></tr></table> <p>The number of <i>MAAR</i> registers included is implementation-dependent but must be an even number in Release 5. Software may write all ones to <i>INDEX</i> to determine the maximum value supported. Other than the all ones, if the value written is not supported, then <i>INDEX</i> is unchanged from its previous value. The register range is always contiguous and starts at value 0.</p>	Encoding	Meaning	0	This register specifies the upper address bound of the <i>MAAR</i> register pair.	1	This register specifies the lower address bound of the <i>MAAR</i> register pair.	R/W	Undefined	Required
Encoding	Meaning										
0	This register specifies the upper address bound of the <i>MAAR</i> register pair.										
1	This register specifies the lower address bound of the <i>MAAR</i> register pair.										

9.56 WatchLo Register (CP0 Register 18)

Compliance Level: *Optional*.

The *WatchLo* and *WatchHi* registers together provide the interface to a watchpoint debug facility which initiates a watch exception if an instruction or data access matches the address specified in the registers. As such, they duplicate some functions of the EJTAG debug solution. Watch exceptions are taken only if the *EXL* and *ERL* bits are zero in the *Status* register. If either bit is a one, the *WP* bit is set in the *Cause* register, and the watch exception is deferred until both the *EXL* and *ERL* bits are zero.

An implementation may provide zero or more pairs of *WatchLo* and *WatchHi* registers, referencing them via the select field of the MTC0/MFC0 and DMTC0/DMFC0 instructions, and each pair of *Watch* registers may be dedicated to a particular type of reference (e.g., instruction or data). Software may determine if at least one pair of *WatchLo* and *WatchHi* registers are implemented via the *WR* bit of the *Config1* register. See the discussion of the *M* bit in the *WatchHi* register description below.

The *WatchLo* register specifies the base virtual address and the type of reference (instruction fetch, load, store) to match. If a particular *Watch* register only supports a subset of the reference types, the unimplemented enables must be ignored on write and return zero on read. Software may determine which enables are supported by a particular *Watch* register pair by setting all three enables bits and reading them back to see which ones were actually set.

It is implementation-dependent whether a data watch is triggered by a prefetch, CACHE, or SYNCI (Release 2 and subsequent releases only) instruction whose address matches the *Watch* register address match conditions. For microMIPS implementations, it is implementation-dependent whether a match occurs if the second half-word overlaps a watched address and the first half-word does not overlap with the watched address.

Figure 9.62 shows the format of the *WatchLo* register; Table 9.80 describes the *WatchLo* register fields.

Figure 9.62 WatchLo Register Format

Table 9.80 WatchLo Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
VAddr	63..3	This field specifies the virtual address to match. Note that this is a doubleword address, since bits [2:0] are used to control the type of match.	R/W	Undefined	Required
I	2	If this bit is one, watch exceptions are enabled for instruction fetches that match the address and are actually issued by the processor (speculative instructions never cause Watch exceptions). If this bit is not implemented, writes to it must be ignored, and reads must return zero.	R/W	0	Optional

Table 9.80 WatchLo Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
R	1	If this bit is one, watch exceptions are enabled for loads that match the address. For the purposes of the MIPS16e PC-relative load instructions, the PC-relative reference is considered to be a data, rather than an instruction reference. That is, the watch-point is triggered only if this bit is a 1. If this bit is not implemented, writes to it must be ignored, and reads must return zero.	R/W	0	Optional
W	0	If this bit is one, watch exceptions are enabled for stores that match the address. If this bit is not implemented, writes to it must be ignored, and reads must return zero.	R/W	0	Optional

9.57 WatchHi Register (CP0 Register 19)

Compliance Level: *Optional*.

The *WatchLo* and *WatchHi* registers together provide the interface to a watchpoint debug facility which initiates a watch exception if an instruction or data access matches the address specified in the registers. As such, they duplicate some functions of the EJTAG debug solution. Watch exceptions are taken only if the *EXL* and *ERL* bits are zero in the *Status* register. If either bit is a one, the *WP* bit is set in the *Cause* register, and the watch exception is deferred until both the *EXL* and *ERL* bits are zero.

An implementation may provide zero or more pairs of *WatchLo* and *WatchHi* registers, referencing them via the select field of the *MTC0/MFC0* and *DMTC0/DMFC0* instructions, and each pair of *Watch* registers may be dedicated to a particular type of reference (e.g., instruction or data). Software may determine if at least one pair of *WatchLo* and *WatchHi* registers are implemented via the *WR* bit of the *Config1* register. If the *M* bit is one in the *WatchHi* register reference with a select field of '*n*', another *WatchHi/WatchLo* pair is implemented with a select field of '*n+1*'.

The *WatchHi* register contains information that qualifies the virtual address specified in the *WatchLo* register: an *ASID*, a *G*(lobal) bit, an optional address mask, and three bits (*I*, *R*, and *W*) that denote the condition that caused the watch register to match. If the *G* bit is one, any virtual address reference that matches the specified address will cause a watch exception. If the *G* bit is a zero, only those virtual address references for which the *ASID* value in the *WatchHi* register matches the *ASID* value in the *EntryHi* register cause a watch exception. The optional mask field provides address masking to qualify the address specified in *WatchLo*.

The *I*, *R*, and *W* bits are set by the processor when the corresponding watch register condition is satisfied and indicate which watch register pair (if more than one is implemented) and which condition matched. When set by the processor, each of these bits remain set until cleared by software. All three bits are “write one to clear”, such that software must write a one to the bit in order to clear its value. The typical way to do this is to write the value read from the *WatchHi* register back to *WatchHi*. In doing so, only those bits which were set when the register was read are cleared when the register is written back.

Figure 9.63 shows the format of the *WatchHi* register; Table 9.81 describes the *WatchHi* register fields.

Figure 9.63 WatchHi Register Format

31	30	29	28	27	26	25	24	23	16				15	12				11	3				2	1	0
M	G	WM	0	EAS	ASID					0					Mask					I	R	W			

Table 9.81 WatchHi Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
M	31	If this bit is one, another pair of <i>WatchHi/WatchLo</i> registers is implemented at an <i>MTC0</i> or <i>MFC0</i> select field value of ' <i>n+1</i> '	R	Preset	Required

Table 9.81 WatchHi Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
G	30	If this bit is one, any address that matches that specified in the <i>WatchLo</i> register will cause a watch exception. If this bit is zero, the <i>ASID</i> field of the <i>WatchHi</i> register must match the <i>ASID</i> field of the <i>EntryHi</i> register to cause a watch exception.	R/W	Undefined	Required
WM	29:28	Reserved for Virtualization Module.	0	0	Reserved
EAS	25:24	If <i>Config4_{AE}</i> = 1 then these bits extend the <i>ASID</i> field of this register. If <i>Config4_{AE}</i> = 0 then Must be written as zero; returns zero on read.	If <i>Config4_A</i> _E = 1 then R/W else 0	If <i>Config4_{AE}</i> = 1 then Undefined else 0	Required
ASID	23..16	ASID value which is required to match that in the <i>EntryHi</i> register if the <i>G</i> bit is zero in the <i>WatchHi</i> register.	R/W	Undefined	Required
Mask	11..3	Optional bit mask that qualifies the address in the <i>WatchLo</i> register. If this field is implemented, any bit in this field that is a one inhibits the corresponding address bit from participating in the address match. If this field is not implemented, writes to it must be ignored, and reads must return zero. Software may determine how many mask bits are implemented by writing ones the this field and then reading back the result.	R/W	Undefined	Optional
I	2	This bit is set by hardware when an instruction fetch condition matches the values in this watch register pair. When set, the bit remains set until cleared by software, which is accomplished by writing a 1 to the bit.	W1C	Undefined	Required (Release 2)
R	1	This bit is set by hardware when a load condition matches the values in this watch register pair. When set, the bit remains set until cleared by software, which is accomplished by writing a 1 to the bit.	W1C	Undefined	Required (Release 2)
W	0	This bit is set by hardware when a store condition matches the values in this watch register pair. When set, the bit remains set until cleared by software, which is accomplished by writing a 1 to the bit.	W1C	Undefined	Required (Release 2)
0	27..26, 15..12	Must be written as zero; returns zero on read.	0	0	Reserved

9.58 XContext Register (CP0 Register 20, Select 0)

Compliance Level: *Required* for 64-bit TLB-based MMUs. *Optional* otherwise.

The *XContext* register is a read/write register containing a pointer to an entry in the page table entry (PTE) array. This array is an operating system data structure that stores virtual-to-physical translations. During a TLB miss, the operating system loads the TLB with the missing translation from the PTE array. The *XContext* register is primarily intended for use with the XTLB Refill handler, but is also loaded by hardware on a TLB Refill. However, it is unlikely to be useful to software in the TLB Refill Handler. The *XContext* register duplicates some of the information provided in the *BadVAddr* register.

If $\text{Config3}_{\text{CTXTC}} = 0$ then the *XContext* register is organized in such a way that the operating system can directly reference a 16-byte structure in memory that describes the mapping. For PTE structures of other sizes, the content of this register can be used by the TLB refill handler after appropriate shifting and masking.

If $\text{Config3}_{\text{CTXTC}} = 0$ then a TLB exception (TLB Refill, XTLB Refill, TLB Invalid, or TLB Modified) causes bits 63..62 of the virtual address to be written into the R field and bits $\text{SEGBITS}-1..13$ of the virtual address to be written into the *BadVPN2* field of the *XContext* register. The *PTEBase* field is written and used by the operating system.

The *BadVPN2* and *R* fields of the *XContext* register are not defined after an address error exception and these fields may be modified by hardware during the address error exception sequence.

Figure 9.64 shows the format of the *XContext* register when $\text{Config3}_{\text{CTXTC}} = 0$; Table 9.82 describes the *XContext* register fields when $\text{Config3}_{\text{CTXTC}} = 0$. In Figure 9.64, bit numbers above the figure use the symbol *SEGBITS*; bit number under the figure assume that *SEGBITS* has the value 40.

Figure 9.64 XContext Register Format when $\text{Config3}_{\text{CTXTC}} = 0$

Table 9.82 XContext Register Fields when $\text{Config3}_{\text{CTXTC}} = 0$

Field		Description	Read / Write	Reset State	Compliance
Name	Bits				
PTEBase	63 .. $\text{SEGBITS}-13+6$ (63..33 assuming <i>SEGBITS</i> is 40)	This field is for use by the operating system and is normally written with a value that allows the operating system to use the <i>XContext</i> Register as a pointer into the current PTE array in memory	R/W	Undefined	Required

Table 9.82 XContext Register Fields when Config3_{CTXTC}=0

Field		Description	Read / Write	Reset State	Compliance										
Name	Bits														
R	SEGBITS-13+5 .. SEGBITS-13+4 (32..31 assuming SEGBITS is 40)	<div>The <i>Region</i> field contains bits 63..62 of the virtual address.</div> <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0b00</td><td>xuseg</td></tr><tr><td>0b01</td><td>xsseg: supervisor address region. If Supervisor Mode is not implemented, this encoding is reserved</td></tr><tr><td>0b10</td><td>Reserved</td></tr><tr><td>0b11</td><td>xkseg</td></tr></table> <div>For processors implementing Config_{AT} = 1 (access to 32-bit compatibility segments only), only the 0b00 and 0b11 values are supplied by the processor on an exception.</div>	Encoding	Meaning	0b00	xuseg	0b01	xsseg: supervisor address region. If Supervisor Mode is not implemented, this encoding is reserved	0b10	Reserved	0b11	xkseg	R	Undefined	Required
Encoding	Meaning														
0b00	xuseg														
0b01	xsseg: supervisor address region. If Supervisor Mode is not implemented, this encoding is reserved														
0b10	Reserved														
0b11	xkseg														
BadVPN2	SEGBITS-13+3 .. 4 (30..4 assuming SEGBITS is 40)	The <i>Bad Virtual Page Number/2</i> field is written by hardware on a miss. It contains bits VA _{SEGBITS-1..13} of the virtual address that missed.	R	Undefined	Required										
0	3..0	Must be written as zero; returns zero on read.	0	0	Reserved										

If *Config3_{CTXTC}* = 1 then the pointer implemented by the *XContext* register can point to any power-of-two-sized PTE structure within memory. This allows the TLB refill handler to use the pointer without additional shifting and masking steps. Depending on the value in the *XContextConfig* register, it may point to an 8-byte pair of 32-bit PTEs within a single-level page table scheme, or to a first level page directory entry in a two-level lookup scheme.

If *Config3_{CTXTC}* = 1 then the a TLB exception (Refill, Invalid, or Modified) causes bits VA_{SEGBITS-1:SEGBITS-(X-Y)} to be written to a variable range of bits “(X-1):Y” of the *XContext* register, where this range corresponds to the contiguous range of set bits in the *XContextConfig* register. The exception causes bits 63..62 of the virtual address to be written into the R field. Bits 63:X+2 are R/W to software, and are unaffected by the exception. Bits Y-1:0 are unaffected by the exception. If X = 31 and Y = 4, i.e. bits 30:4 are set in *XContextConfig*, the behavior is identical to the standard MIPS III *XContext* register (bits 30:4 are filled with VA_{39:13} when SEGBITS equals 40). Although the fields have been made variable in size and interpretation, the MIPS64 nomenclature is retained. Bits 63:X are referred to as the *PTEBase* and R fields, and bits X-1:Y are referred to as *BadVPN2*.

The value of the *XContext* register is **UNPREDICTABLE** following a modification of the contents of the *XContextConfig* register.

Figure 9.65 shows the format of the *XContext* Register when *Config3_{CTXTC}* = 1; Table 9.83 describes the *XContext* register fields *Config3_{CTXTC}* = 1.

0	Variable, (Y-1):0 where Y in {63:1}. May be null.	Must be written as zero; returns zero on read.	R or R/W	0 (if R) or Undefined (if R/W)	Reserved										

9.59 Reserved for Implementations (CP0 Register 22, all Select values)

Compliance Level: *Implementation Dependent.*

CP0 register 22 is reserved for implementation-dependent use and is not defined by the architecture.

9.60 Debug Register (CP0 Register 23, Select 0)

Compliance Level: *Optional.*

The *Debug* register is part of the EJTAG specification. Refer to that specification for the format and description of this register.

9.61 Debug2 Register (CP0 Register 23, Select 6)

Compliance Level: *Optional*.

The *Debug2* register is part of the EJTAG specification. Refer to that specification for the format and description of this register.

9.62 DEPC Register (CP0 Register 24)

Compliance Level: *Optional.*

The *DEPC* register is a read-write register that contains the address at which processing resumes after a debug exception has been serviced. It is part of the EJTAG specification and the reader is referred there for the format and description of the register. All bits of the *DEPC* register are significant and must be writable.

When a debug exception occurs, the processor writes the *DEPC* register with,

- the virtual address of the instruction that was the direct cause of the exception, or
- the virtual address of the immediately preceding branch or jump instruction, when the exception causing instruction is in a branch delay slot, and the *Branch Delay* bit in the *Cause* register is set.

The processor reads the *DEPC* register as the result of execution of the DERET instruction.

Software may write the *DEPC* register to change the processor resume address and read the *DEPC* register to determine at what address the processor will resume.

9.62.1 Special Handling of the DEPC Register in Processors That Implement the MIPS16e ASE or microMIPS64 Base Architecture

In processors that implement the MIPS16e ASE or the microMIPS64 base architecture, the *DEPC* register requires special handling.

When the processor writes the *DEPC* register, it combines the address at which processing resumes with the value of the *ISA Mode* register:

$$DEPC \leftarrow \text{resumePC}_{63..1} \parallel \text{ISAMode}_0$$

“resumePC” is the address at which processing resumes, as described above.

When the processor reads the *DEPC* register, it distributes the bits to the *PC* and *ISA Mode* registers:

$$\begin{aligned} PC &\leftarrow DEPC_{63..1} \parallel 0 \\ \text{ISAMode} &\leftarrow DEPC_0 \end{aligned}$$

Software reads of the *DEPC* register simply return to a GPR the last value written with no interpretation. Software writes to the *DEPC* register store a new value which is interpreted by the processor as described above.

9.63 Performance Counter Register (CP0 Register 25)

Compliance Level: *Recommended.*

The Architecture supports implementation-dependent performance counters that provide the capability to count events or cycles for use in performance analysis. If performance counters are implemented, each performance counter consists of a pair of registers: a 32-bit control register and a 32-bit or 64-bit counter register. To provide additional capability, multiple performance counters may be implemented.

Performance counters can be configured to count implementation-dependent events or cycles under a specified set of conditions that are determined by the control register for the performance counter. The counter register increments once for each enabled event. When the most-significant bit of the counter register is a one (the counter overflows), the performance counter optionally requests an interrupt. In implementations of Release 1 of the Architecture, this interrupt is combined in a implementation-dependent way with hardware interrupt 5. In Release 2 of the Architecture, pending interrupts from all performance counters are ORed together to become the *PCI* bit in the *Cause* register, and are prioritized as appropriate to the interrupt mode of the processor. Counting continues after a counter register overflow whether or not an interrupt is requested or taken.

Each performance counter is mapped into even-odd select values of the *PerfCnt* register: Even selects access the control register and odd selects access the counter register. [Table 9.84](#) shows an example of two performance counters and how they map into the select values of the *PerfCnt* register.

Table 9.84 Example Performance Counter Usage of the PerfCnt CP0 Register

Performance Counter	PerfCnt Register Select Value	PerfCnt Register Usage
0	PerfCnt, Select 0	Control Register 0
	PerfCnt, Select 1	Counter Register 0
1	PerfCnt, Select 2	Control Register 1
	PerfCnt, Select 3	Counter Register 1

More or less than two performance counters are also possible, extending the select field in the obvious way to obtain the desired number of performance counters. Software may determine if at least one pair of Performance Counter Control and Counter registers is implemented via the *PC* bit in the *Config1* register. If the *M* bit is one in the Performance Counter Control register referenced via a select field of '*n*', another pair of Performance Counter Control and Counter registers is implemented at the select values of '*n*+2' and '*n*+3'.

The Control Register associated with each performance counter controls the behavior of the performance counter. [Figure 9.66](#) shows the format of the Performance Counter Control Register; [Table 9.85](#) describes the Performance Counter Control Register fields.

Figure 9.66 Performance Counter Control Register Format

Table 9.85 Performance Counter Control Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance						
Name	Bits										
M	31	If this bit is a one, another pair of Performance Counter Control and Counter registers is implemented at an MTC0 or MFC0 select field value of ‘n+2’ and ‘n+3’.	R	Preset by hardware	Required						
W	30	Specifies the width of the corresponding Counter register, as follows: <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>Width of the corresponding Counter register is 32 bits</td></tr><tr><td>1</td><td>Width of the corresponding Counter register is 64 bits</td></tr></table>	Encoding	Meaning	0	Width of the corresponding Counter register is 32 bits	1	Width of the corresponding Counter register is 64 bits	R	Preset by hardware	Required (Release 2)
Encoding	Meaning										
0	Width of the corresponding Counter register is 32 bits										
1	Width of the corresponding Counter register is 64 bits										
Impl	29:25	This field is implementation-dependent and is not specified by the architecture. If not used by the implementation, must be written as zero; returns zero on read.		Undefined 0 if not used by the implementation	Optional						
EC	24..23	Reserved for Virtualization Module.	0	0	Reserved						
0	22..16	Must be written as zero; returns zero on read	0	0	Reserved						
PCTD	15	Performance Counter Trace Disable. The PDTrace facility (revision 6.00 and higher) has the ability to trace Performance Counter in its output. This bit is used to disable the specified performance counter from being traced when performance counter trace is enabled and a performance counter trace event is triggered. <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>Tracing is enabled for this counter.</td></tr><tr><td>1</td><td>Tracing is disabled for this counter.</td></tr></table>	Encoding	Meaning	0	Tracing is enabled for this counter.	1	Tracing is disabled for this counter.	RW	0	Required if PDTrace Performance Counter Tracing feature is implemented.
Encoding	Meaning										
0	Tracing is enabled for this counter.										
1	Tracing is disabled for this counter.										
EventExt	14..11	In some implementations which support more than the 64 encodings possible in the 6-bit Event field, the EventExt field acts as an extension to the Event field. In such instances the event selection is the concatenation of the two fields, i.e., EventExt Event. The actual field width is implementation-dependent. Any bits that are not implemented read as zero and are ignored on write.	RW	Undefined	Optional						

Table 9.85 Performance Counter Control Register Field Descriptions (Continued)

Fields		Description	Read / Write	Reset State	Compliance						
Name	Bits										
Event	10..5	Selects the event to be counted by the corresponding Counter Register. The list of events is implementation-dependent, but typical events include cycles, instructions, memory reference instructions, branch instructions, cache and TLB misses, etc. Implementations that support multiple performance counters allow ratios of events, e.g., cache miss ratios if cache miss and memory references are selected as the events in two counters	R/W	Undefined	Required						
IE	4	Interrupt Enable. Enables the interrupt request when the corresponding counter overflows (the most-significant bit of the counter is one. This is bit 31 for a 32-bit wide counter or bit 63 of a 64-bit wide counter, denoted by the W bit in this register). Note that this bit simply enables the interrupt request. The actual interrupt is still gated by the normal interrupt masks and enable in the <i>Status</i> register. <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>Performance counter interrupt disabled</td></tr><tr><td>1</td><td>Performance counter interrupt enabled</td></tr></table>	Encoding	Meaning	0	Performance counter interrupt disabled	1	Performance counter interrupt enabled	R/W	0	Required
Encoding	Meaning										
0	Performance counter interrupt disabled										
1	Performance counter interrupt enabled										
U	3	Enables event counting in User Mode. Refer to Section 3.4 “User Mode” on page 24 for the conditions under which the processor is operating in User Mode. <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>Disable event counting in User Mode</td></tr><tr><td>1</td><td>Enable event counting in User Mode</td></tr></table>	Encoding	Meaning	0	Disable event counting in User Mode	1	Enable event counting in User Mode	R/W	Undefined	Required
Encoding	Meaning										
0	Disable event counting in User Mode										
1	Enable event counting in User Mode										
S	2	Enables event counting in Supervisor Mode (for those processors that implement Supervisor Mode). Refer to Section 3.3 “Supervisor Mode” on page 24 for the conditions under which the processor is operating in Supervisor mode. If the processor does not implement Supervisor Mode, this bit must be ignored on write and return zero on read. <table><tr><th>Encoding</th><th>Meaning</th></tr><tr><td>0</td><td>Disable event counting in Supervisor Mode</td></tr><tr><td>1</td><td>Enable event counting in Supervisor Mode</td></tr></table>	Encoding	Meaning	0	Disable event counting in Supervisor Mode	1	Enable event counting in Supervisor Mode	R/W	Undefined	Required

The Counter Register associated with each performance counter increments once for each enabled event. [Figure 9.67](#) shows the format of the Performance Counter Counter Register; [Table 9.86](#) describes the Performance Counter Counter Register fields.

Figure 9.67 Performance Counter Counter Register Format

Table 9.86 Performance Counter Counter Register Field Descriptions

Fields		Description	Read/ Write	Reset State	Compliance
Name	Bits				
Event Count	31..0 or 63..0	<p>Increments once for each event that is enabled by the corresponding Control Register. When the most-significant bit is one, a pending interrupt request is ORed with those from other performance counters and indicated by the PCI bit in the <i>Cause</i> register.</p> <p>The width of the counter is either 32 bits or 64 bits depending on the value of the <i>W</i> bit in the corresponding Performance Counter Control Register.</p>	R/W	Undefined	Required

Programming Note:

In Release 2 of the Architecture, the EHB instruction can be used to make interrupt state changes visible when the IE field of the Control register or the Event Count Field of the Counter register are written. See [SECTION 6.1.2.1 “Software Hazards and the Interrupt System”](#) on page 96.

9.64 ErrCtl Register (CP0 Register 26, Select 0)

Compliance Level: *Optional.*

The *ErrCtl* register provides an implementation-dependent diagnostic interface with the error detection mechanisms implemented by the processor. This register has been used in previous implementations to read and write parity or ECC information to and from the primary or secondary cache data arrays in conjunction with specific encodings of the Cache instruction or other implementation-dependent method. The exact format of the *ErrCtl* register is implementation-dependent and not specified by the architecture. Refer to the processor specification for the format of this register and a description of the fields.

9.65 CacheErr Register (CP0 Register 27, Select 0)

Compliance Level: *Optional.*

The *CacheErr* register provides an interface with the cache error detection logic that may be implemented by a processor.

The exact format of the *CacheErr* register is implementation-dependent and not specified by the architecture. Refer to the processor specification for the format of this register and a description of the fields.

9.66 TagLo Register (CP0 Register 28, Select 0, 2)

Compliance Level: *Required* if a cache is implemented; *Optional* otherwise.

The *TagLo* and *TagHi* registers are read/write registers that act as the interface to the cache tag array. The Index Store Tag and Index Load Tag operations of the CACHE instruction use the *TagLo* and *TagHi* registers as the source or sink of tag information, respectively.

The exact format of the *TagLo* and *TagHi* registers is implementation-dependent. Refer to the processor core specification for the format of this register and a description of the register fields. However, in all implementations, software must be able to write zeros into the *TagLo* and *TagHi* registers, and then use the Index Store Tag cache operation to initialize the cache tags to a valid state at power-up.

It is implementation-dependent whether there is a single *TagLo* register that acts as the interface to all caches, or a dedicated *TagLo* register for each cache. If multiple *TagLo* registers are implemented, they occupy the even select values for this register encoding, with select 0 addressing the instruction cache and select 2 addressing the data cache. Whether individual *TagLo* registers are implemented or not for each cache, processors must accept a write of zero to select 0 and select 2 of *TagLo* as part of the software process of initializing the cache tags at powerup.

Figure 9-68 Example TagLo Register Format

63	8	7	6	5	4	3	2	1	0
PTagLo				PState	L	Impl	0	P	

Table 9.87 Example TagLo Register Field Descriptions

Fields		Description	Read/ Write	Reset State	Compliance
Name	Bits				
PTagLo	63..8	Specifies the upper address bits of the cache tag. Refer to the processor-specific description for the detailed definition.	R/W	Undefined	Optional
PState	7:6	Specifies the state bits for the cache tag. Refer to the processor-specific description for the detailed definition.	R/W	Undefined	Optional
L	5	Specifies the lock bit for the cache tag. Refer to the processor-specific description for the detailed definition.	R/W	Undefined	Optional
Impl	4:3	This field is reserved for implementations.		Undefined	Optional
0	2:1	Must be written as zero; returns zero on read.	0	0	Reserved
P	0	Specifies the parity bit for the cache tag. Refer to the processor-specific description for the detailed definition.	R/W	Undefined	Optional

9.67 DataLo Register (CP0 Register 28, Select 1, 3)

Compliance Level: *Optional.*

The *DataLo* and *DataHi* registers are registers that act as the interface to the cache data array and are intended for diagnostic operation only. The Index Load Tag operation of the CACHE instruction reads the corresponding data values into the *DataLo* and *DataHi* registers.

The exact format and operation of the *DataLo* and *DataHi* registers is implementation-dependent. Refer to the processor specification for the format of this register and a description of the fields.

It is implementation-dependent whether there is a single *DataLo* register that acts as the interface to all caches, or a dedicated *DataLo* register for each cache. If multiple *DataLo* registers are implemented, they occupy the odd select values for this register encoding, with select 1 addressing the instruction cache and select 3 addressing the data cache.

9.68 TagHi Register (CP0 Register 29, Select 0, 2)

Compliance Level: *Required* if a cache is implemented; *Optional* otherwise.

The *TagLo* and *TagHi* registers are read/write registers that act as the interface to the cache tag array. The Index Store Tag and Index Load Tag operations of the CACHE instruction use the *TagLo* and *TagHi* registers as the source or sink of tag information, respectively.

The exact format of the *TagLo* and *TagHi* registers is implementation-dependent. Refer to the processor specification for the format of this register and a description of the fields. However, software must be able to write zeros into the *TagLo* and *TagHi* registers and use the Index Store Tag cache operation to initialize the cache tags to a valid state at powerup.

It is implementation-dependent whether there is a single *TagHi* register that acts as the interface to all caches, or a dedicated *TagHi* register for each cache. If multiple *TagHi* registers are implemented, they occupy the even select values for this register encoding, with select 0 addressing the instruction cache and select 2 addressing the data cache. Whether individual *TagHi* registers are implemented or not for each cache, processors must accept a write of zero to select 0 and select 2 of *TagHi* as part of the software process of initializing the cache tags at powerup.

9.69 DataHi Register (CP0 Register 29, Select 1, 3)

Compliance Level: *Optional.*

The *DataLo* and *DataHi* registers are registers that act as the interface to the cache data array and are intended for diagnostic operation only. The Index Load Tag operation of the CACHE instruction reads the corresponding data values into the *DataLo* and *DataHi* registers.

The exact format and operation of the *DataLo* and *DataHi* registers is implementation-dependent. Refer to the processor specification for the format of this register and a description of the fields.

9.70 ErrorEPC (CP0 Register 30, Select 0)

Compliance Level: Required.

The *ErrorEPC* register is a read-write register, similar to the *EPC* register, at which processing resumes after a Reset, Soft Reset, Nonmaskable Interrupt (NMI) or Cache Error exceptions (collectively referred to as error exceptions). Unlike the *EPC* register, there is no corresponding branch delay slot indication for the *ErrorEPC* register. All bits of the *ErrorEPC* register are significant and must be writable.

When an error exception occurs, the processor writes the *ErrorEPC* register with:

- the virtual address of the instruction that was the direct cause of the exception, or
- the virtual address of the immediately preceding branch or jump instruction when the error causing instruction is in a branch delay slot.

The processor reads the *ErrorEPC* register as the result of execution of the ERET instruction.

Software may write the *ErrorEPC* register to change the processor resume address and read the *ErrorEPC* register to determine at what address the processor will resume

Figure 9.69 shows the format of the *ErrorEPC* register; Table 9.88 describes the *ErrorEPC* register fields.

Figure 9.69 ErrorEPC Register Format

Table 9.88 ErrorEPC Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
ErrorEPC	63..0	Error Exception Program Counter	R/W	Undefined	Required

9.70.1 Special Handling of the ErrorEPC Register in Processors That Implement the MIPS16e ASE or microMIPS64 Base Architecture

In processors that implement the MIPS16e ASE or microMIPS64 base architecture, the *ErrorEPC* register requires special handling.

When the processor writes the *ErrorEPC* register, it combines the address at which processing resumes with the value of the *ISA Mode* register:

$$\text{ErrorEPC} \leftarrow \text{resumePC}_{63..1} \parallel \text{ISAMode}_0$$

“resumePC” is the address at which processing resumes, as described above.

When the processor reads the *ErrorEPC* register, it distributes the bits to the *PC* and *ISAMode* registers:

$$\begin{aligned} \text{PC} &\leftarrow \text{ErrorEPC}_{63..1} \parallel 0 \\ \text{ISAMode} &\leftarrow \text{ErrorEPC}_0 \end{aligned}$$

Software reads of the *ErrorEPC* register simply return to a GPR the last value written with no interpretation. Software writes to the *ErrorEPC* register store a new value which is interpreted by the processor as described above.

9.71 DESAVE Register (CP0 Register 31)

Compliance Level: *Optional.*

The *DESAVE* register is part of the EJTAG specification. Refer to that specification for the format and description of this register.

The *DESAVE* register is meant to be used solely while in Debug Mode. If kernel mode software uses this register, it would conflict with debugging kernel mode software. For that reason, it is strongly recommended that kernel mode software not use this register. If the *KScratch** registers are implemented, kernel software can use those registers. (For Release 6, the *KScratch** registers are mandatory.)

9.72 KScratchn Registers (CP0 Register 31, Selects 2 to 7)

Compliance Level: **Pre-Release 6** - *Optional, KScratch1 and KScratch2 at selects 2, 3 are recommended.*
Release 6 - *Required.*

The *KScratchn* registers are read/write registers available for scratch pad storage by kernel mode software. These registers are 32bits in width for 32-bit processors and 64bits for 64-bit processors.

The existence of these registers is indicated by the *KScrExist* field within the *Config4* register. The *KScrExist* field specifies which of the selects are populated with a kernel scratch register.

Debug Mode software should not use these registers, instead debug software should use the *DESAVE* register. If EJTAG is implemented, select 0 should not be used for a *KScratch* register. Select 1 is being reserved for future debug use and should not be used for a *KScratch* register.

Figure 9.70 KScratchn Register Format

Table 9.89 KScratchn Register Field Descriptions

Fields		Description	Read / Write	Reset State	Compliance
Name	Bits				
Data	63:0	Scratch pad data saved by kernel software.	R/W	Undefined	Optional (Pre-Release 6) Required (Release 6)

Alternative MMU Organizations

The main body of this specification describes the TLB-based MMU organization. This appendix describes other potential MMU organizations.

A.1 Fixed Mapping MMU

As an alternative to the full TLB-based MMU, the MIPS64/microMIPS64 Architecture supports a lightweight memory management mechanism with fixed virtual-to-physical address translation, and no memory protection beyond what is provided by the address error checks required of all MMUs. This may be useful for those applications which do not require the capabilities of a full TLB-based MMU. It is not anticipated that MIPS64 processors that implement a fixed-mapping MMU will require a 64-bit address capability. As a result, the description below is given assuming a 32-bit address.

A.1.1 Fixed Address Translation

Address translation using the Fixed Mapping MMU is done as follows:

- Kseg0 and Kseg1 addresses are translated in an identical manner to the TLB-based MMU: they both map to the low 512MB of physical memory.
- Useg/Suseg/Kuseg addresses are mapped by adding 1GB to the virtual address when the *ERL* bit is zero in the Status register, and are mapped using an identity mapping when the *ERL* bit is one in the Status register.
- Sseg/Ksseg/Kseg2/Kseg3 addresses are mapped using an identity mapping.

Supervisor Mode is not supported with a Fixed Mapping MMU.

Table A.1 lists all mappings from virtual to physical addresses. Note that address error checking is still done before the translation process. Therefore, an attempt to reference kseg0 from User Mode still results in an address error exception, just as it does with a TLB-based MMU.

Table A.1 Physical Address Generation from Virtual Addresses

Segment Name	Virtual Address	Generates Physical Address	
		Status _{ERL} = 0	Status _{ERL} = 1
useg suseg kuseg	0x0000 0000 through 0x7FFF FFFF	0x4000 0000 through 0xBFFF FFFF	0x0000 0000 through 0x7FFF FFFF
kseg0	0x8000 0000 through 0x9FFF FFFF	0x0000 0000 through 0x1FFF FFFF	

Table A.1 Physical Address Generation from Virtual Addresses (Continued)

Segment Name	Virtual Address	Generates Physical Address	
		Status _{ERL} = 0	Status _{ERL} = 1
kseg1	0xA000 0000 through 0xBFFF FFFF	0x0000 0000 through 0x0x1FFF FFFF	
sseg ksseg kseg2	0xC000 0000 through 0xDFFF FFFF	0xC000 0000 through 0xDFFF FFFF	
kseg3	0xE000 0000 through 0xFFFF FFFF	0xE000 0000 through 0xFFFF FFFF	

Note that this mapping means that physical addresses 0x2000 0000 through 0x3FFF FFFF are inaccessible when the *ERL* bit is off in the *Status* register, and physical addresses 0x8000 0000 through 0xBFFF FFFF are inaccessible when the *ERL* bit is on in the *Status* register.

[Figure A.1](#) shows the memory mapping when the *ERL* bit in the *Status* register is zero; [Figure A.2](#) shows the memory mapping when the *ERL* bit is one.

Figure A.1 Memory Mapping when ERL = 0

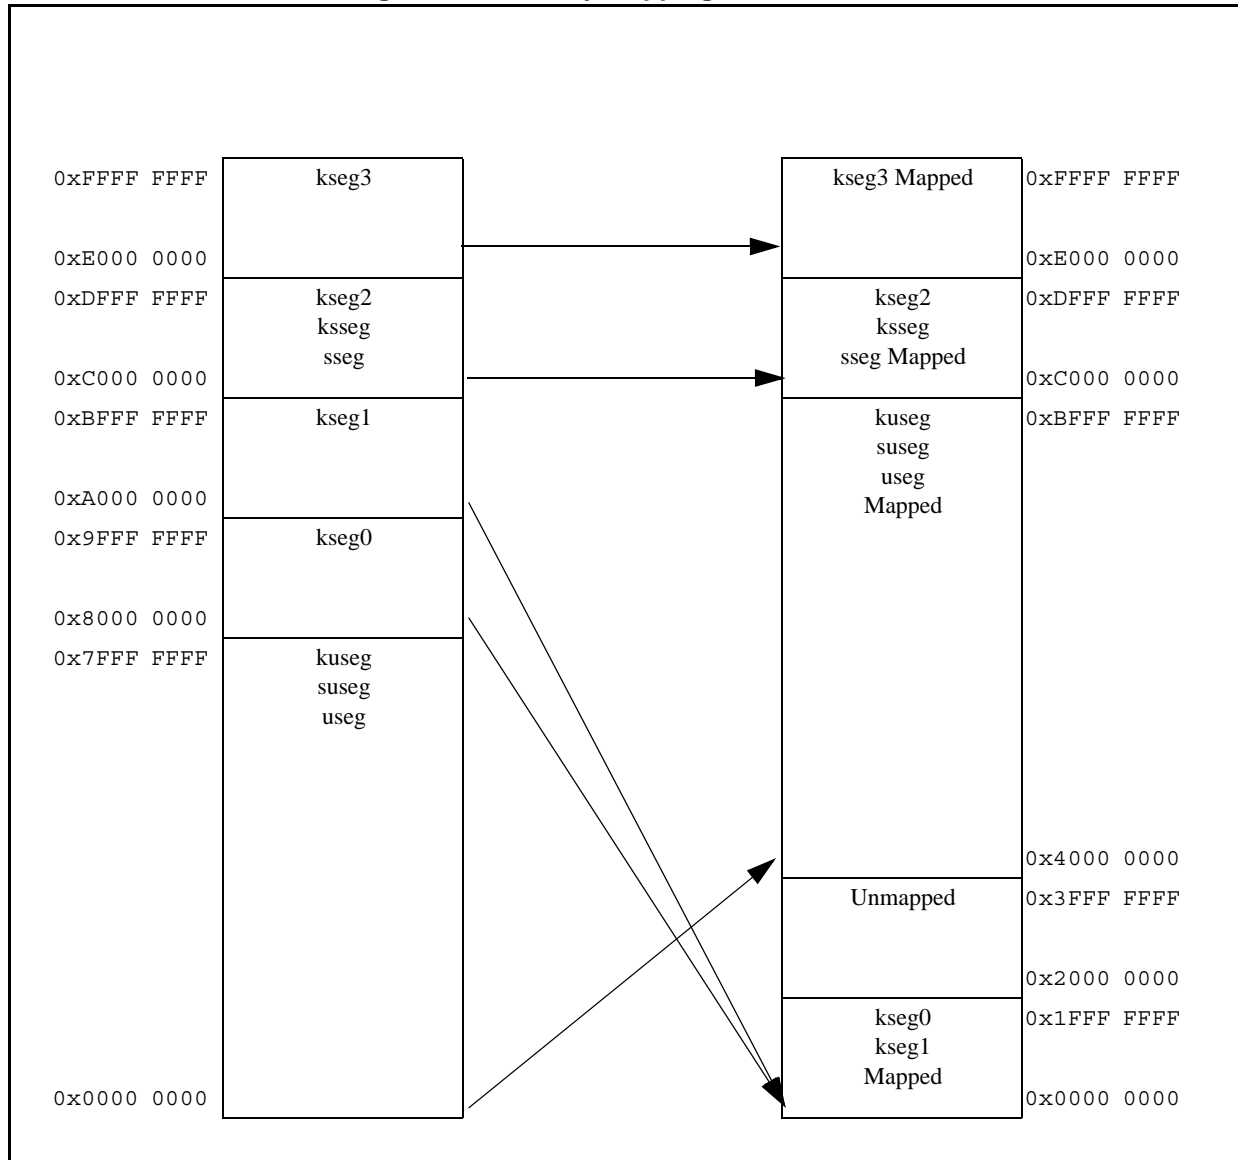

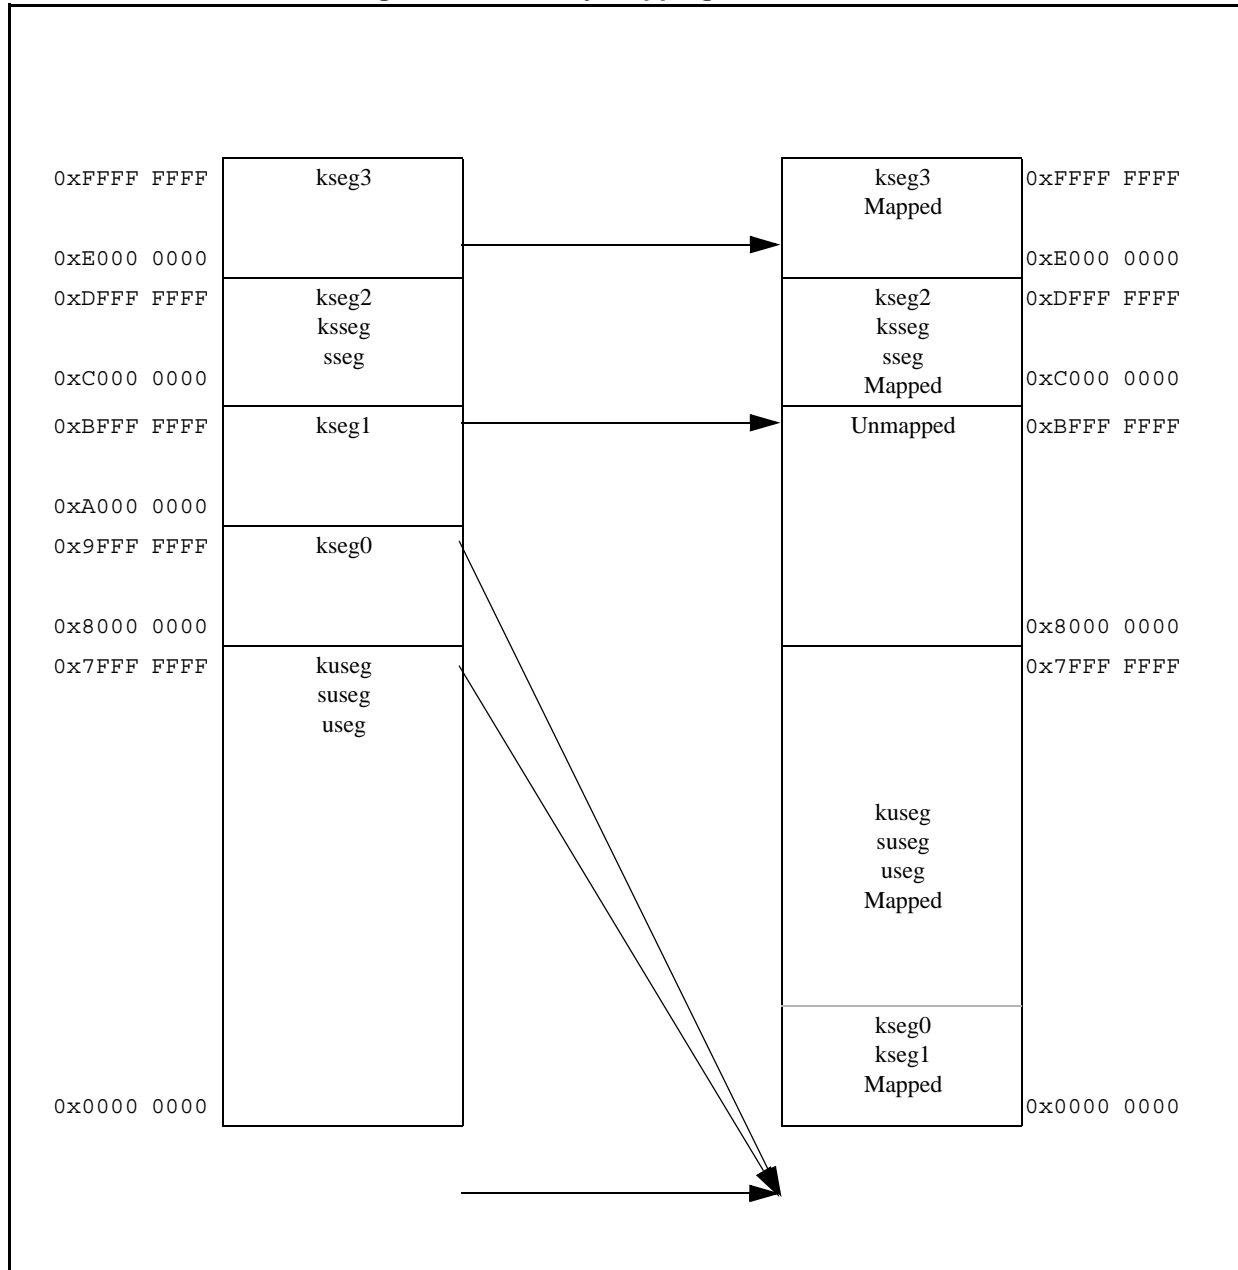

Figure A.2 Memory Mapping when ERL = 1

A.1.2 Cacheability Attributes

Because the TLB provided the cacheability attributes for the kuseg, kseg2, and kseg3 segments, some mechanism is required to replace this capability when the fixed mapping MMU is used. Two additional fields are added to the *Config* register whose encoding is identical to that of the *K0* field. These additions are the *K23* and *KU* fields which control the cacheability of the kseg2/kseg3 and the kuseg segments, respectively. Note that when the *ERL* bit is on in the *Status* register, kuseg data references are always treated as uncacheable references, independent of the value of the *KU* field. The operation of the processor is **UNDEFINED** if the *ERL* bit is set while the processor is executing instructions from kuseg.

The cacheability attributes for `kseg0` and `kseg1` are provided in the same manner as for a TLB-based MMU: the cacheability attribute for `kseg0` comes from the `K0` field of *Config*, and references to `kseg1` are always uncached.

Figure A.3 shows the format of the additions to the *Config* register; Table A.2 describes the new *Config* register fields.

Figure A.3 Config Register Additions

31	30	28	27	25	24	16	15	14	13	12	10	9	7	6	4	3	2	0
M	K23	KU		0		BE	AT	AR		MT		0		VI		K0		

Table A.2 Config Register Field Descriptions

Fields		Description	Read/ Write	Reset State	Compliance
Name	Bits				
K23	30:28	Kseg2/Kseg3 cacheability and coherency attribute. See Table 9.11 on page 150 for the encoding of this field.	R/W	Undefined	Required
KU	27:25	Kuseg cacheability and coherency attribute when <i>Status_{ERL}</i> is zero. See Table 9.11 on page 150 for the encoding of this field.	R/W	Undefined	Required

A.1.3 Changes to the CP0 Register Interface

Relative to the TLB-based address translation mechanism, the following changes are necessary to the CP0 register interface:

- The *Index*, *Random*, *EntryLo0*, *EntryLo1*, *Context*, *PageMask*, *Wired*, and *EntryHi* registers are no longer required and may be removed. Pre-Release 6, the effects of a read or write to these registers are **UNDEFINED**. For Release 6, writes to these registers are ignored, reads return 0 as if the registers were Reserved for Architecture.
- The TLBWR, TLBWI, TLBP, and TLBR instructions are no longer required and must cause a Reserved Instruction Exception.

A.2 Block Address Translation

This section describes the architecture for a block address translation (BAT) mechanism that reuses much of the hardware and software interface that exists for a TLB-Based virtual address translation mechanism. This mechanism has the following features:

- It preserves as much as possible of the TLB-Based interface, both in hardware and software.
- It provides independent base-and-bounds checking and relocation for instruction references and data references.
- It provides optional support for base-and-bounds relocation of `kseg2` and `kseg3` virtual address regions.

A.2.1 BAT Organization

The BAT is an indexed structure which is used to translate virtual addresses. It contains pairs of instruction/data entries which provide the base-and-bounds checking and relocation for instruction references and data references, respectively. Each entry contains a page-aligned bounds virtual page number, a base page frame number (whose

width is implementation-dependent), a cache coherence field (C), a dirty (D) bit, and a valid (V) bit. [Figure A.4](#) shows the logical arrangement of a BAT entry.

Figure A.4 Contents of a BAT Entry

The BAT is indexed by the reference type and the address region to be checked as shown in [Table A.3](#).

Table A.3 BAT Entry Assignments

Entry Index	Reference Type	Address Region
0	Instruction	useg/kuseg
1	Data	
2	Instruction	kseg2 (or kseg2 and kseg3)
3	Data	
4	Instruction	kseg3
5	Data	

Entries 0 and 1 are required. Entries 2, 3, 4 and 5 are optional and may be implemented as necessary to address the needs of the particular implementation. If entries for kseg2 and kseg3 are not implemented, it is implementation-dependent how, if at all, these address regions are translated. One alternative is to combine the mapping for kseg2 and kseg3 into a single pair of instruction/data entries. Software may determine how many BAT entries are implemented by looking at the MMU Size field of the *Config1* register.

A.2.2 Address Translation

When a virtual address translation is requested, the BAT entry that is appropriate to the reference type and address region is read. If the virtual address is greater than the selected bounds address, or if the valid bit is off in the entry, a TLB Invalid exception of the appropriate reference type is initiated. If the reference is a store and the D bit is off in the entry, a TLB Modified exception is initiated. Otherwise, the base PFN from the selected entry, shifted to align with bit 12, is added to the virtual address to form the physical address. The BAT process can be described as follows:

```

i ← SelectIndex (reftype, va)
bounds ← BAT[i]BoundsVPN || 112
pfn ← BAT[i]BasePFN
c ← BAT[i]C
d ← BAT[i]D
v ← BAT[i]V
if (va > bounds) or (v = 0) then
    InitiateTLBInvalidException(reftype)
endif
if (d = 0) and (reftype = store) then
    InitiateTLBModifiedException()
endif
pa ← va + (pfn || 012)
  
```

Making all addresses out-of-bounds can only be done by clearing the valid bit in the BAT entry. Setting the bounds value to zero leaves the first virtual page mapped.

A.2.3 Changes to the CP0 Register Interface

Relative to the TLB-based address translation mechanism, the following changes are necessary to the CP0 register interface:

- The *Index* register is used to index the BAT entry to be read or written by the TLBWI and TLBR instructions.
- The *EntryHi* register is the interface to the BoundsVPN field in the BAT entry.
- The *EntryLo0* register is the interface to the BasePFN and C, D, and V fields of the BAT entry. The register has the same format as for a TLB-based MMU.
- The *Random*, *EntryLo1*, *Context*, *PageMask*, and *Wired* registers are eliminated. Pre-Release 6 the effects of a read or write to these registers are **UNDEFINED**. For Release 6, writes to these registers are ignored, reads return 0 as if the registers were Reserved for Architecture.
- The TLBP and TLBWR instructions are unnecessary. The TLBWI and TLBR instructions reference the BAT entry whose index is contained in the *Index* register. The effects of executing a TLBP or TLBWR are **UNDEFINED**, but processors should signal a Reserved Instruction Exception.

A.3 Dual Variable-Page-Size and Fixed-Page-Size TLBs

Most MIPS CPU cores implement a fully associative Joint TLB. Unfortunately, such fully-associative structures can be slow, can require a large amount of logic components to implement and can dissipate a lot of power. The number of entries for a fully associative array that can be practically implemented is not large.

In high performance systems, it is desirable to minimize the frequency of TLB misses. In small and low-cost systems, it is desirable to keep the implementation costs of a TLB to a minimum. This section describes an optional alternative MMU configuration which decreases the implementation costs of a small TLB as well as allows for a TLB that can map a very large number of pages to be reasonably implemented.

A.3.1 MMU Organization

This alternative MMU configuration uses two TLB structures.

1. This first TLB is called the Fixed-Page-Size TLB or the FTLB.
 - At any one time, all entries within the FTLB use a shared, common page size.
 - The FTLB is not fully-associative, but rather set associative.
 - The number of ways per set is implementation specific.
 - The number of sets is implementation specific.
 - The common page size is also implementation specific.

Alternative MMU Organizations

- The common page size is allowed to be software configurable. The choice of the common page size is done once for the entire FTLB, not on a per-entry basis. This configuration by software can only be done after a full flush/initialization of the FTLB, before there are any valid entries within the FTLB. Implementations are also allowed to support only one page size for the FTLB - in that case, the FTLB page size is fixed by hardware and not software configurable.
 - The EHINV TLB invalidate feature is required for FTLB implementation. The legacy method of using reserved address values to represent invalid TLB entries is not guaranteed to work where the implementation can limit what addresses are allowable at a specific TLB index.
2. The second TLB is called the Variable-Page-Size TLB or the VTLB.
- The choice of page size is done on a per-entry basis. That is, one VTLB entry can use a page size that is different from the size used by another VTLB entry.
 - The VTLB is fully-associative.
 - The number of entries is implementation specific.
 - The set of allowable page sizes for VTLB entries is implementation specific.

Just as for the JTLB, both the FTLB and VTLB are shared between the instruction stream and the data stream. For address translation, the virtual address is presented to both the FTLB and VTLB in parallel. Entries in both structures are accessed in parallel to search for the physical address.

The use of two TLB structures has these benefits:

- The implementation costs of building a set-associative TLB with many entries can be much less than that of implementing a large fully-associative TLB.
- The existence of a VTLB retains the capability of using large pages to map large sections of physical memory without consuming a large number of entries in the FTLB.

Random replacement of pages in the MMU happens mainly in the FTLB. In most operating systems, on-demand paging only uses one page size so the FTLB is sufficient for this purpose. Some of the address bits of the specified virtual address are used to index into the FTLB as appropriate for the chosen FTLB array size. The method of choosing which FTLB way to modify is implementation specific.

The VTLB is very similar to the JTLB. The *CO_PageMask* register is used to program the page size used for a particular VTLB entry.

The configuration of the FTLB is reflected in the FTLB fields within the new *Config4* register. The size of the VTLB is reflected in the *Config1_{MMUSize-1}* field. The presence of the dual FTLB and VTLB is denoted by the value of 0x4 in *Config_{MT}* register field. These registers are described in [“Changes to the COP0 Registers” on page 357](#).

Most implementations would choose to build a VTLB with a smaller number of entries and a FTLB with a larger number of entries. This combination allows for many on-demand fixed-sized pages as well as for a small number of large address blocks to be simultaneously mapped by the MMU.

A.3.2 Programming Interface

The software programming interface used for the fully-associative JTLB is maintained as much as possible to decrease the amount of software porting.

Also for that purpose, each entry in the FTLB as well as the VTLB use one tag (VPN2) to map two physical pages (PFN), just as in the JTLB. The entries in either array are accessed through the *C0_EntryHi* and *C0_EntryLo0/1* registers.

Entries in either array (FTLB or VTLB) can be accessed with the TLBWI and TLBWR instructions.

The *PageMask* register is used to set the page size for the VTLB entries. This register is also used to choose which array (FTLB or VTLB) to write for the TLBWR instruction.

For the rest of this section, the following parameters are used:

3. FPageSize - the page size used by the FTLB entries
4. FSetSize - Number of entries in one way of the FTLB.
5. FWays - Number of ways within a set of the FTLB.
6. VIndex - Number of entries in the VTLB.

For the *C0_Index*, the *C0_Wired* registers, the TLBP, TLBR and TLBWI instructions; the VTLB occupies indices 0 to VIndex-1. The FTLB occupies indices VIndex to VIndex + (FSetSize * FWays)-1.

The TLBP instruction produces a value which can be used by the TLBWI instruction without modification by software. When referring to the FTLB, the value is the concatenation of the selected FTLB way and set, and incremented by the size of the VTLB. For example, {selected FTLB Way, selected FTLB Set} + VIndex.

If *C0_PageMask* is set to the page size used by the FTLB, the TLBWR instruction modifies entries within the FTLB or the VTLB. It is implementation specific whether the VTLB will be modified for this case.

How the FTLB set-associative array is indexed is implementation specific. In any indexing scheme, the least significant address bit that can be used for indexing is $\log_2(\text{FPageSize})+1$. The number of index bits needed to select the correct set within the FTLB array is $\log_2(\text{FSetSize})$.

Since the FTLB array can be modified through the TLBWI instruction, it is possible for software to choose an inappropriate FTLB index value for the specified virtual address. In this case, it is implementation specific whether a Machine Check exception is generated for the TLBWI instruction.

The EHINV TLB entry invalidate feature is required for a FTLB. Since it is implementation defined as to whether a particular FTLB index value can be used for a specific virtual address, the legacy method of representing an invalid TLB entry by using a predefined address value is not guaranteed to work.

The method of choosing which FTLB way to modify is implementation specific.

If *C0_PageMask* is not set to the page size used by the FTLB, the TLBWR instruction modifies entries within the VTLB. The VTLB entry to be written is specified by the $\log_2(\text{VIndex})$ least significant bits of the *C0_Random* register value.

Alternative MMU Organizations

For both the TLBWR and TLBWI instruction, it is implementation specific whether both (FTLB and VTLB) arrays are checked for duplicate or overlapping entries and whether a Machine Check exception is generated for these cases.

A.3.2.1 Example with chosen FTLB and VTLB sizes

As an example, let's assume an implementation chooses these values:

1. FPageSize - 4 kB used by the FTLB entries
2. FSetSize - 128 in one way of the FTLB.
3. FWays - 4 ways within a set of the FTLB. (The FTLB has (128 sets x 4 ways/set) 512 entries, capable of mapping (512 entries x 2 pages/entry x 4 kB/page) 4MB of address space simultaneously.
4. VIndex - 8 entries in the VTLB.

For the *CO_Index*, the *CO_Wired* registers, the TLBP, TLBR and TLBWI instructions; the VTLB occupies indices 0 to 7. The FTLB occupies indices 8 to 519.

The FTLB entries have a VPN2 field which starts at virtual address bit 12.

The least significant virtual address bit that can be used for FTLB indexing is virtual address 13. To index the FTLB set-associative array, 7 index bits are needed.

In this simple example, the design uses contiguous virtual address bits directly for indexing the FTLB (it does not create a hash for the FTLB indexing). The FTLB set-associative array is indexed using virtual address bits 19:13. The TLBWR instruction uses these address bits held in *CO_EntryHi*.

In this simple example, the design uses a cycle counter of 2 bits for way selection within the FTLB.

The *Random* register field within *CO_Random* is 3 bits wide to select the entry within the VTLB.

A.3.3 Changes to the TLB Instructions

TLBP

Both the VTLB and the FTLB are probed in parallel for the specified virtual address.

If the address hits in the VTLB, *CO_Index* specifies the entry within the VTLB (a value within 0 to VIndex-1).

If the address hits in the FTLB, *CO_Index* specifies the entry within the FTLB (a value within VIndex to VIndex+(FSetSize * FWays)-1). Which bits are used to encode the selected FTLB set as opposed to which bits are used to encode the selected FTLB way is implementation specific, but must match what is expected by the TLBWI instruction implementation. *CO_PageMask* reflects the page size used by the FTLB.

TLBR

Either a VTLB entry or a FTLB entry is read depending on the specified index in *CO_Index*.

Index values of 0 to VIndex-1 access the VTLB. Index values VIndex to VIndex+(FSetSize * FWays)-1 access the FTLB.

TLBWI

Either the VTLB or FTLB entry is written depending on the specified index in *C0_Index*.

Index values of 0 to VIndex-1 access the VTLB. Index values VIndex to VIndex+(FSetSize * FWays)-1 access the FTLB.

It is implementation specific if the hardware checks the *VPN2* field of *C0_EntryHi* is appropriate for the specified set within the FTLB. The implementation may generate a machine-check exception if the *VPN2* field is not appropriate for the specified set.

It is implementation-specific if the hardware checks both arrays (FTLB and VTLB) for valid duplicate or overlapping entries and if the hardware signals a Machine Check exception for these cases.

TLBWR

Either the VTLB or FTLB entry is written depending on the specified page size in *C0_PageMask*.

If *C0_PageMask* is set to any page size other than that used by the FTLB, the TLBWR instruction modifies a VTLB entry. The VTLB entry is specified by the Random register field within *C0_Random*.

If *C0_PageMask* is set to the page size used by the FTLB, the TLBWR modifies either a FTLB entry or a VTLB entry. It is implementation specific which array is modified. The FTLB set-associative array is indexed in an implementation-specific manner.

The method of selecting which FTLB way to modify is implementation specific.

It is implementation specific if the hardware checks both arrays (FTLB and VTLB) for valid duplicate or overlapping entries and if the hardware signals a Machine Check exception for these cases.

A.3.4 Changes to the COP0 Registers

C0_Config4 (CP0 Register 16, Select 4)

A new register introduced to reflect the FTLB configuration. *Config4_{MMUExtDef}* register field must be set to a value of 2 or 3 to reflect that the Dual VTLB and FTLB configuration is implemented. If either *Config4* is not implemented or the *Config4_{MMUExtDef}* field is not fixed to 2 or 3, the Dual VTLB/FTLB configuration is not implemented.

If *Config4_{MMUExtDef}* is fixed to a value of 2 or 3, the *FTLBPageSize*, *FTLBWays* and *FTLBSets* fields reflect the FTLB configuration. Please refer to “[Configuration Register 4 \(CP0 Register 16, Select 4\)](#)” on page 279 for more detail on this register.

For Release 6, *Config4_{MMUExtDef}* is reserved; see the description for the *Config4* register.

C0_Config1 (CP0 Register 16, Select 1)

If *Config4_{MMUExtDef}* is fixed to a value of 2 or 3, the *MMUSize-1* register field is redefined to reflect only the size of the VTLB.

C0_Config (CP0 Register 16, Select 0)

If *Config_{MT}* is fixed to a value of 4, the implemented MMU Type is the dual FTLB and VTLB configuration.

C0_Index (CP0 Register 0, Select 0)

If *Config4_{MMUExtDef}* is fixed to a value of 2 or 3, the register is redefined in this way:

The value held in the Index field can refer to either an entry in the FTLB or the VTLB. Index values of 0 to VIndex-1 access the VTLB. Index values VIndex to VIndex+(FSetSize * FWays)-1 access the FTLB.

Which bits in the register field which encode the FTLB set as opposed to which bits encode the FTLB way is implementation specific, but must match what is expected by the TLBWI instruction implementation.

C0_Random (CP0 Register 1, Select 0)

For Release 6, this register has been deprecated.

If *Config4_{MMUExtDef}* is fixed to a value of 2 or 3, the register is redefined in this way:

If the value in *C0_PageMask* is not set to the page-size used by the FTLB, and a TLBWR instruction is executed, a VTLB entry is modified. The Random register field is used to select the VTLB entry which is modified.

If the value in *C0_PageMask* is set to the page-size used by the FTLB, and a TLBWR instruction is executed, a FTLB entry or a VTLB entry is modified. It is implementation specific whether the *C0_RANDOM* register is used to select the FTLB entry.

The upper bound of the *Random* register field value is VIndex.

C0_Wired (CP0 Register 6, Select 0)

If *Config4_{MMUExtDef}* is fixed to a value of 2 or 3, the *Wired* register field can only hold a value of VIndex-1 or less. That is, only VTLB entries can be wired down.

C0_PageMask (CP0 Register 5, Select 0)

If *Config4_{MMUExtDef}* is fixed to a value of 2 or 3, the register is redefined in this way:

The *Mask* and *MaskX* field values determine whether the VTLB or the FTLB is modified by a TLBWR instruction.

The *Mask* and *MaskX* register fields do not affect the TLB address match operation for FTLB entries. The page size used by the FTLB entries are specified by the *Config4_{FPageSize}* register field.

The software writeable bits in the *Mask* and *MaskX* fields reflect what page sizes are available in the VTLB. These fields do not reflect the page sizes which are available in the FTLB.

A.3.5 Software Compatibility

One of the main software visible changes introduced by this alternative MMU are the values reported in the *C0_Index* register. Previously, it was just a simple linear index. For this alternative MMU configuration, the value reflects both a selected way as well as a selected set when a FTLB entry is specified.

Fortunately, this Index value isn't frequently generated by software nor read by software. Instead, the contents of the *CO_Index* register is generated by hardware upon a TLBP instruction. Software then just issues the TLBWI instruction once the *CO_EnLo** registers have been appropriately modified.

Another software visible change is that the *MMUSize-1* field no longer reports the entire MMU size. For TLB initialization and TLB flushing, the contents of *Config1_{MMUSize-1}*, *Config4_{FTLBWays}* and *Config4_{FTLBSets}* register fields must all be read to calculate the entire number of TLB entries that must be initialized. TLB initialization and flushing are the only times software needs to generate an Index value to write into the *CO_Index* register.

Only the VTLB entries may be wired down. This limitation is due to using some of the *EntryHi* VPN2 bits to index the FTLB array.

If a page using the FTLB page-size is to be wired down, that page must be programmed into the VTLB using the TLBWI instruction, as the TLBWR instruction would only access the FTLB in that situation and could not access any wired-down TLB entry. The TLBWI instruction is normally used for wired-down pages, so this restriction should not affect existing software.

The EHINV TLB entry invalidate feature is required for a FTLB. Since it is implementation-defined as to whether a particular FTLB index value can be used for a specific virtual address, the legacy method of representing an invalid TLB entry by using a predefined address value is not guaranteed to work.

Revision History

Revision	Date	Description
0.92	January 20, 2001	Internal review copy of reorganized and updated architecture documentation.
0.95	March 12, 2001	Clean up document for external review release
1.00	August 29, 2002	Update based on review feedback: <ul style="list-style-type: none"> • Change ProbEn to ProbeTrap in the EJTAG Debug entry vector location discussion. • Add cache error and EJTAG Debug exceptions to the list of exceptions that do not go through the general exception processing mechanism. • Fix incorrect branch offset adjustment in general exception processing pseudo code to deal with extended MIPS16e instructions. • Add Config_{VI} to denote an instruction cache with both virtual indexing and virtual tags. • Correct XContext register description to note that both BadVPN2 and R fields are UNPRE-DICTABLE after an address error exception. • Note that Supervisor Mode is not supported with a Fixed Mapping MMU. • Define TagLo bits 4..3 as implementation-dependent. • Describe the intended usage model differences between Reset and Soft Reset Exceptions. • Correct the minimum number of TLB entries to be 3, not 2, and show an example of the need for 3. • Modify the description of PageMask and the TLB lookup process to acknowledge the fact that not all implementations may support all page sizes.
1.90	September 1, 2002	Update the specification with the changes introduced in Release 2 of the Architecture. Changes in this revision include: <ul style="list-style-type: none"> • The following new Coprocessor 0 registers were added: EBase, HWREna, IntCtl, PageGrain, SRSCtl, SRSTMap. • The following Coprocessor 0 registers were modified: Cause, Config, Config2, Config3, EntryHi, EntryLo0, EntryLo1, PageMask, PerfCnt, Status, WatchHi, WatchLo. • The descriptions of Virtual memory, exceptions, and hazards have been updated to reflect the changes in Release 2. • A chapter on GPR shadow registers has been added. • The chapter on CP0 hazards has been completely rewritten to reflect the Release 2 changes.

Revision History

Revision	Date	Description
2.00	June 9, 2003	<p>Complete the update to include Release 2 changes. These include:</p> <ul style="list-style-type: none"> • Make bits 12..11 of the PageMask register power up zero and be gated by 1K page enable. This eliminates the problem of having these bits set to 0b11 on a Release 2 chip in which kernel software has not enabled 1K page support. • Correct the address of the cache error vector when the BEV bit is 1. It should be 0xBFC0.0300, not 0xBFC0.0200. • Correct the introduction to shadow registers to note that the SRSCtl register is not updated at the end of an exception in which <i>Status_{BEV}</i> = 1. • Clarify that a MIPS16e PC-relative load reference is a data reference for the purposes of the <i>Watch</i> registers. • Add note about a hardware interrupt being deasserted between the time that the processor detects the interrupt request and the time that the software interrupt handler runs. Software must be prepared for this case and simply dismiss the interrupt via an ERET. • Add restriction that software must set EBase_{15..12} to zero in all bit positions less than or equal to the most significant bit in the vector offset. This is only required in certain combinations of vector number and vector spacing when using VI or EIC Interrupt modes. • Add suggested software TLB init routine which reduced the probability of triggering a machine check.
2.50	July 1, 2005	<p>Changes in this revision:</p> <ul style="list-style-type: none"> • Correct the encoding table description for the <i>Cause_{PCI}</i> bit to indicate that the bit controls the performance counter, not the timer interrupt. • Correct the figure Interrupt Generation for External Interrupt Controller Interrupt Mode to show Cause_{IP1..0} going to the EIC, rather than Status_{IP1..0} • Update all files to FrameMaker 7.1. • Update reset exception list to reflect missing Release 2 reset requirements. • Define bits 31..30 in the <i>HWREna</i> register as access enables for the implementation-dependent hardware registers 31 and 30. • Add definition for Coprocessor 0 Enable to Operating Modes chapter. • Add K23 and KU fields to main Config register definition as a pointer to the Fixed Mapping MMU appendix. • Add specific note about the need to implement all shadow sets between 0 and HSS - no holes are allowed. • Change the hazard from a software write to the SRSCtl_{pss} field and a RDPGPR and WRP-GPR and instruction hazard vs. an execution hazard. • Correct the pseudo-code in the cache error exception description to reflect the Release 2 change that introduced EBase. • Document that EHB clears instruction state change hazards for writes to interrupt-related fields in the <i>Status</i>, <i>Cause</i>, <i>Compare</i>, and <i>PerfCnt</i> registers. • Note that implementation-dependent bits in the <i>Status</i> and <i>Config</i> registers should be defined in such a way that standard boot software will run, and that software which preserves the value of the field when writing the registers will also run correctly. • With Release 2 of the Architecture the FR bit in the <i>Status</i> register should be a R/W bit, not a R bit. • Improve the organization of the CP0 hazards table, and document that DERET, ERET, and exceptions and interrupts clear all hazards before the instruction fetch at the target instruction. • Add list of MIPS® MT CP0 registers and MIPS MT and MIPS® DSP present bits in the <i>Config3</i> register.

Revision	Date	Description
2.60	June 25, 2008	<p>Changes in this revision:</p> <ul style="list-style-type: none"> • Add the <i>UserLocal</i> register and access to it via the RDHWR instruction. • Operating Modes - footnote about kseg/sseg • COP3 no longer usable for customer extensions • EIC Mode allows VectorNum != RIPL • CP0Regs Table - added missing EJTAG & PDTrace Registers • <i>CO_DataLo/Hi</i> are actually R/W • Hazards table - added a bunch of missing ones • Various typos fixed.
2.61	August 01, 2008	<ul style="list-style-type: none"> • In the <i>Status</i> register description, the ERL behavior description was incorrect in saying only 29 bits of kuseg becomes uncached and unmapped.
2.62	January 2, 2009	<ul style="list-style-type: none"> • CCRes is accessed through \$3 not \$4 - <i>HWENA</i> register affected. • PCTD bit added to <i>CO_PerfCtl</i>.
2.70	January 22, 2009	<p>MIPS Technologies-only release for internal review:</p> <ul style="list-style-type: none"> • Added BigPages feature - Pages larger than 256MB are supported. <i>CO_PageMask</i> and <i>CO_Config3</i> affected. • Added CP0 Reg 31, Select 2 & 3 as kernel scratch registers. • Added VTLB/FTLB optional MMU configuration to Appendix A and <i>Config4</i> register for these new MMU configurations • Added CDMM chapter, <i>CDMMBase</i> COP0 Register, CDMM bit in <i>CO_Config3</i>, FDCI bit in <i>CO_Cause</i> register and IPFDC field in <i>IntCtl</i> register.
2.71	January 28, 2009	<p>MIPS Technologies-only release for internal review:</p> <ul style="list-style-type: none"> • EIC mode - revision 2.70, was actually missing the new option of EIC driving an explicit vector offset (not using VectorNumbers). • Clarified the text and diagrams for the 3 EIC options - RIPL=VectorNum, Explicit VectorNum; Explicit VectorOffset.
2.72	April 20, 2009	<p>MIPS Technologies-only release for internal review:</p> <ul style="list-style-type: none"> • Table was incorrectly saying ECR_{ProbEn} selected debug exception Vector. Changed to ECR_{ProbTrap}. • Added MIPS Technologies traditional meanings for CCA values. • Added list of COP2 instruction to COPUnusable Exception description. • Added statement that only uncached access is allowed to CDMM region. • Updated Exception Handling Operation pseudo-code for EIC Option_3 (EIC sends entire vector). •
2.73	April 22, 2009	<p>MIPS Technologies-only release for internal review:</p> <ul style="list-style-type: none"> • Fixed comments for ASE.
2.74	June 03, 2009	<p>MIPS Technologies-only release for internal review:</p> <ul style="list-style-type: none"> • Added CDMM Enable Bit in <i>CDMMBase</i> COP0 register • Reserved CCA values can be used to init TLB; just can't be used for mapping.
2.75	June 12, 2009	<p>MIPS Technologies-only release for internal review:</p> <ul style="list-style-type: none"> • <i>CDMMBase_Upper_Address</i> Field doesn't have a fixed reset value. • Added DSP State Disabled Exception to <i>CO_Cause</i> Exception Type table.
2.80	July 20, 2009	<ul style="list-style-type: none"> • FTLB and VTLB MMU configuration denoted by 0x4 in <i>ConfigMT</i> • Added TLBP -> TLBWI hazard • Added KScrExist field in <i>Config4</i>.

Revision History

Revision	Date	Description
2.81	September 22, 2009	MIPS Technologies-only release for internal review: <ul style="list-style-type: none"> ContextConfig Register description added. Context Register description updated for SmartMIPS behavior. EntryLo* register descriptions updated for RI & XI bits. TLB description and pseudo-code updated for RI & XI bits. PageMask register updated for RIE and XIE bits. Config3 register updated for CTXTC and RXI bits. Reserve MCU ASE bits in C0_Cause and C0_Status. Clean up description for KScratch registers - selects 2&3 are recommended, but additional scratch registers are allowed.
2.82	January 19, 2010	MIPS Technologies-only release for internal review: <ul style="list-style-type: none"> Added Debug2 register.
3.00	March 8, 2010	<ul style="list-style-type: none"> RI/XI feature moved from SmartMIPS ASE. microMIPS features added MCU ASE features added. XI and RI exceptions can be programmed to use their own exception codes instead of using TLBL code. XI and RI can be independently implemented as XIE and RIE bits are allowed to be Read-Only. TCOpt Register added to C0 Register list. Added encoding (0x7) for 32 sets for one cache way.
3.05	July 07, 2010	<ul style="list-style-type: none"> CMGCRBase register added. Lower bits of C0_Context register allowed to be write-able if Config3.CTXTC=1 and Config3.SM=0.
3.10	July 27, 2010	<ul style="list-style-type: none"> Add XContextConfig register. Explain the limits of the BadVPN2 field within Context and XContext registers and the relationships with the writable bits within ContextConfig and XContextConfig registers.
3.11	April 24, 2011	MIPS Technologies-only release for internal review: <ul style="list-style-type: none"> FPR registers are UNPREDICTABLE after change of Status.FR bit. 1004K did not support CCA=0 Config4 - KScratch Registers, mention that select 1 is reserved for future debugger use. Context Register - the bit subscripts describing which VA bits go into the BadVPN2 field was incorrect for the case when the ContextConfig register is used. The correct VA bits are 31:31-((X-Y)-1) for MIPS32, 63:63-((X-Y)-1) for MIPS64.
3.12	April 28, 2011	<ul style="list-style-type: none"> XContext & XContextConfig registers - be more explicit of the SEGBITS limitations. ContextConfig Register is only 32-bits in width to be more compatible to MIPS32.
3.13	November 10, 2011	MIPS Technologies-only release for internal review: <ul style="list-style-type: none"> MIPS32 compatibility location for RI/XI EntryLo bits. Nested Exception handling support. Config5 register added.
3.14	February 17, 2012	MIPS Technologies-only release for internal review: <ul style="list-style-type: none"> Segmentation Control, EVA scheme added: <ol style="list-style-type: none"> Adds SegCf0, SegCf1, SegCf2 registers SegCtl - Modifies EBase, Config3. TLB Invalidate feature.
3.50	September 20, 2012	<ul style="list-style-type: none"> Added BadInstr & BadInstrP registers. Added extended ASID field in EntryHi and WatchHi. Added Hardware Page Table Walking Feature
3.51	October 2, 2012	MIPS Technologies-only release for internal review: <ul style="list-style-type: none"> Hardware Page Table Walker - previous description wasn't fully correct. PTEVld bit is only used for Directory PTE entries as leaf PTE entries are always loaded from memory. Added TLB init routine for SegmentationControl/EVA.

Revision	Date	Description
3.52	November 12, 2012	<ul style="list-style-type: none"> • SegCtl Overlay segment(s) are available in kernelmode. Re-iterate that. • FTLB/VTLB - if PageMask set to FTLB size, allowed to modify VTLB. • implementation-dependent whether <i>Watch</i> Registers match on 2nd half of microMIPS instruction. • Hardware Page Table Walker - added option so Directory PTE entries can represent power-of-4 memory region, using Dual Page Method. • Optional PageGrain.MCCause field to record different types of Machine Check Exceptions.
5.00	December 14, 2012	<ul style="list-style-type: none"> • R5 changes - include MSA and Virtualization registers and control bits in Register table. • R5 changes - include MSA and Virtualization exceptions in Cause exception types. • R5 changes - MT and DSP ASEs -> Modules • R5 changes - MDMX now deprecated. • “Preset” -> “Preset by hardware”
5.01	December 16, 2012	<ul style="list-style-type: none"> • No technical content change: • Update cover logos • Update copyright text
5.02	April 2012	<ul style="list-style-type: none"> • R5 changes: FR=1 64-bit FPU register model required is required, if floating-point is supported. Section 3.5.2 64-bit FPR Enable. Table 9.41 Status Register Field Descriptions, FR (floating-point register mode) bit. • R5 extension: Table 9.57 Config Register Field Descriptions, AR bit (Architecture revision level). AR=1 indicates Release 2 or Release 3 or Release 5. Like Release 3, all features introduced in Release 5 are optional. • Correction: Table 9.59 BPG, Big Pages feature, not supported in MIPS32, only in MIPS64
5.03	September 9, 2013	<ul style="list-style-type: none"> • Update document template to reflect new ownership by Imagination Technologies.
5.04	September 29, 2013	<p>MAAR initial version</p> <ul style="list-style-type: none"> • Add MAAR, MAARI and Config5.MRP • Table 1.1 typo. Speculate=1 should not contain comment about oldest in machine. Meaningful to Speculate=0. Moved outside sub-table. • Added a condition to sw write of MAARI.Index - write of all 1s returns the largest value supported.
5.04	November 12, 2013	<p>XPA initial Version.</p> <ul style="list-style-type: none"> • Add extended EntryLo0/1, LLAddr, TagLo, CDMMBase, CMGCRBase • PageGrain.ELPA, Config3.LPA, Config5.MVH • Remove comment about SW having to initialize the extension bits (of EntryLo,TagLo) if PageGrain.ELPA=0. HW had been asked to reset to 0, but the current POR solution is for mtc0 to 0 out the extension bits that are writable. HW is responsible for zeroing out read-only bits on operation that updates the bits. • Remove CDMMBase and CMGCRBase from list of COP0 registers requiring extensions. The two registers support up to 36b PA which is sufficient for their purpose. Less testing. • Add a config bit, Config5.MVH, for mth/mfhc0. Since mth/mfhc0 may be used independently of XPA in the future, it is easier for software to query one bit instead of multiple. Further Config3.LPA=1 on 64-bit HW need not mean mthc0/mfhc0 are implemented.

Revision History

Revision	Date	Description
6.00	March 31, 2014	<ul style="list-style-type: none"> Removed <i>Random</i> register. Removed <i>Status_{RP}</i> bit. Removed <i>Status_{TS}</i> bit. <i>Coprocessor 0</i> <i>UserLocal</i>, <i>BidInstr</i>, <i>BadInstrP</i>, and <i>KScratchn</i> bits now are required. <i>Index</i>: If value greater than, or equal to, the number of TLB entries is written, HW leaves this register unchanged. <i>EntryLoC</i>: HW must ignore writes of unsupported values of this field. <i>UserLocal</i>: now required, and <i>Config3_{ULRI}</i> must be 1. <i>PageMask</i>: HW ignores writes of unsupported values to the <i>Mask</i> field. <i>PageGrain</i>, <i>EntryLo0/1</i>, <i>PageMask</i>, <i>EntryHi</i>: no longer required to write specified values to certain fields and flush TLB before changing a value in this register. SW must now must invalidate TLB entries explicitly using TLBWI. <i>PWField</i>: writing unsupported values to this register leaves it unmodified. <i>PWSize_{PTW}</i>: write of 0 value is ignored. <i>PWSize_{PTEI}</i>: write of unsupported value does not modify register. <i>Wired</i>: hardware ignores writes of unsupported values to the <i>Wired</i> field. <i>Wired</i>: added a required <i>Limit</i> bit field. <i>RDHWR_{ULR}</i>: now required. <i>BadInstr</i>: now required. <i>BadInstrP</i>: now required. <i>Status_{CU}</i>: change in field size. <i>Status</i> bit 28: new name and changed functionality. <i>Status</i> bit 27: new name and changed functionality. <i>Status_{FR}</i>: FR= 1 now mandatory; FR = 0 now obsolete. <i>Status</i> bit 25 and bit 21: now reserved. <i>Status_{SR}</i> and <i>Status_{NMI}</i>: HW ignores a write of 1; ; now R/W0 (see Table 9.2). <i>Status_{KSU}</i>: HW ignores a write of the value. <i>IntCtl_{VS}</i>: HW ignores writes of reserved values. <i>Cause_{WP}</i>: HW ignores a write of 1; now R/W0 (see Table 9.2). <i>Config_{AR}</i>: now required. Also, encoding 2 has changed. <i>Config3_{BP}</i> and <i>Config3_{BJ}</i>: must now be 1. <i>Cofig3_{ULRI}</i> and <i>Cofig3_{RXI}</i>: now required. <i>Config4</i>: format and functionality has changed significantly. <i>Config5_{SBR}</i>: new field. <i>KScratchn</i>: now required. <i>Config_{K0/K23/KU}</i>, <i>SegCth</i>, <i>CFGn_C</i>: hardware ignores writes of unsupported values to the C field. <i>COP0Index</i>: Clarification - h/w clears <i>Index_P</i> while s/w can only set to 1. <i>COP0 PWField_{PTEI}</i> <ul style="list-style-type: none"> Reset value changed to 2. Clarified that 0,1 values are illegal, 2 is required, all other values are optional and implementation-specific. <i>PTEI</i> will be unchanged if an unsupported value is written.

Revision	Date	Description
6.01	October 17, 2014	<ul style="list-style-type: none"> Added <i>Global Number</i> register for R6 multi-threading support. Added <i>Config5_{VP}</i> for R6 multi-threading support. Added Modeless Evil Twin support: <i>Config5_{UFE/FRE}</i>. Updated MIPS64 <i>Status_{KX/SX/UX}</i> for Release 6 handling; added table describing the prioritization of <i>Status_{KX/SX/UX}</i>. Made minor change to reset state of <i>PWSize_{PTW}</i>. Made minor changes to reset state in all fields of <i>PWField</i>; added clarifications to <i>PWField_{PTEI}</i>. Added <i>Config5_{L2C}</i> to detect presence of L2 Config2 in <i>COP0</i>. Modified <i>PageMask</i> to eliminate 1 kB pages; added optional small page support. <i>EBaseCPUNum</i>: in Release 6 with multi-threading, this is replaced by VPNum. Updated CP0 <i>MAAR</i>. <ul style="list-style-type: none"> Default is not to speculate If an address is to speculate, it must be specified by <i>MAAR</i>. Addresses outside of the <i>MAAR</i> range cannot speculate. Updated COP0 <i>LLAddr</i> and <i>Config5_{LLB}</i> to indicated both the LLAddr and LLB fields are mandatory for R6. Added Section 4.11 - new requirements for 32-bit addressing compatibility in MIPS64. Updated <i>Status_{KX/SX/UX/PX}</i> with clarifications of legacy behavior and new requirements for 32-bit addressing compatibility in MIPS64. Added <i>Config5_{DEC/CES}</i> for endian switching capability.
6.02	July 10, 2015	<ul style="list-style-type: none"> Added CP0 BEVVA, DebugContextID (new) Added CP0 VPControl for MT (new) Updated HWREna with PerfCtr, XNP capabilities (new) Updated Config5 - rm CES and added XNP.
